# List of Registers

<b>The Cortex-M3 Processor .....</b>	<b>55</b>
Register 1: Cortex General-Purpose Register 0 (R0) .....	62
Register 2: Cortex General-Purpose Register 1 (R1) .....	62
Register 3: Cortex General-Purpose Register 2 (R2) .....	62
Register 4: Cortex General-Purpose Register 3 (R3) .....	62
Register 5: Cortex General-Purpose Register 4 (R4) .....	62
Register 6: Cortex General-Purpose Register 5 (R5) .....	62
Register 7: Cortex General-Purpose Register 6 (R6) .....	62
Register 8: Cortex General-Purpose Register 7 (R7) .....	62
Register 9: Cortex General-Purpose Register 8 (R8) .....	62
Register 10: Cortex General-Purpose Register 9 (R9) .....	62
Register 11: Cortex General-Purpose Register 10 (R10) .....	62
Register 12: Cortex General-Purpose Register 11 (R11) .....	62
Register 13: Cortex General-Purpose Register 12 (R12) .....	62
Register 14: Stack Pointer (SP) .....	63
Register 15: Link Register (LR) .....	64
Register 16: Program Counter (PC) .....	65
Register 17: Program Status Register (PSR) .....	66
Register 18: Priority Mask Register (PRIMASK) .....	70
Register 19: Fault Mask Register (FAULTMASK) .....	71
Register 20: Base Priority Mask Register (BASEPRI) .....	72
Register 21: Control Register (CONTROL) .....	73
<b>Cortex-M3 Peripherals .....</b>	<b>97</b>
Register 1: SysTick Control and Status Register (STCTRL), offset 0x010 .....	108
Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014 .....	110
Register 3: SysTick Current Value Register (STCURRENT), offset 0x018 .....	111
Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100 .....	112
Register 5: Interrupt 32-47 Set Enable (EN1), offset 0x104 .....	113
Register 6: Interrupt 0-31 Clear Enable (DIS0), offset 0x180 .....	114
Register 7: Interrupt 32-47 Clear Enable (DIS1), offset 0x184 .....	115
Register 8: Interrupt 0-31 Set Pending (PEND0), offset 0x200 .....	116
Register 9: Interrupt 32-47 Set Pending (PEND1), offset 0x204 .....	117
Register 10: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280 .....	118
Register 11: Interrupt 32-47 Clear Pending (UNPEND1), offset 0x284 .....	119
Register 12: Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300 .....	120
Register 13: Interrupt 32-47 Active Bit (ACTIVE1), offset 0x304 .....	121
Register 14: Interrupt 0-3 Priority (PRI0), offset 0x400 .....	122
Register 15: Interrupt 4-7 Priority (PRI1), offset 0x404 .....	122
Register 16: Interrupt 8-11 Priority (PRI2), offset 0x408 .....	122
Register 17: Interrupt 12-15 Priority (PRI3), offset 0x40C .....	122
Register 18: Interrupt 16-19 Priority (PRI4), offset 0x410 .....	122
Register 19: Interrupt 20-23 Priority (PRI5), offset 0x414 .....	122
Register 20: Interrupt 24-27 Priority (PRI6), offset 0x418 .....	122
Register 21: Interrupt 28-31 Priority (PRI7), offset 0x41C .....	122
Register 22: Interrupt 32-35 Priority (PRI8), offset 0x420 .....	122

Register 23:	Interrupt 36-39 Priority (PRI9), offset 0x424 .....	122
Register 24:	Interrupt 40-43 Priority (PRI10), offset 0x428 .....	122
Register 25:	Interrupt 44-47 Priority (PRI11), offset 0x42C .....	122
Register 26:	Software Trigger Interrupt (SWTRIG), offset 0xF00 .....	124
Register 27:	CPU ID Base (CPUID), offset 0xD00 .....	125
Register 28:	Interrupt Control and State (INTCTRL), offset 0xD04 .....	126
Register 29:	Vector Table Offset (VTABLE), offset 0xD08 .....	129
Register 30:	Application Interrupt and Reset Control (APINT), offset 0xD0C .....	130
Register 31:	System Control (SYSCTRL), offset 0xD10 .....	132
Register 32:	Configuration and Control (CFGCTRL), offset 0xD14 .....	134
Register 33:	System Handler Priority 1 (SYSPRI1), offset 0xD18 .....	136
Register 34:	System Handler Priority 2 (SYSPRI2), offset 0xD1C .....	137
Register 35:	System Handler Priority 3 (SYSPRI3), offset 0xD20 .....	138
Register 36:	System Handler Control and State (SYSHNDCTRL), offset 0xD24 .....	139
Register 37:	Configurable Fault Status (FAULTSTAT), offset 0xD28 .....	143
Register 38:	Hard Fault Status (HFAULTSTAT), offset 0xD2C .....	149
Register 39:	Memory Management Fault Address (MMADDR), offset 0xD34 .....	150
Register 40:	Bus Fault Address (FAULTADDR), offset 0xD38 .....	151
Register 41:	MPU Type (MPUTYPE), offset 0xD90 .....	152
Register 42:	MPU Control (MPUCTRL), offset 0xD94 .....	153
Register 43:	MPU Region Number (MPUNUMBER), offset 0xD98 .....	155
Register 44:	MPU Region Base Address (MPUBASE), offset 0xD9C .....	156
Register 45:	MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4 .....	156
Register 46:	MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC .....	156
Register 47:	MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4 .....	156
Register 48:	MPU Region Attribute and Size (MPUATTR), offset 0xDA0 .....	158
Register 49:	MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8 .....	158
Register 50:	MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0 .....	158
Register 51:	MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8 .....	158
<b>System Control .....</b>		<b>173</b>
Register 1:	Device Identification 0 (DID0), offset 0x000 .....	188
Register 2:	Brown-Out Reset Control (PBORCTL), offset 0x030 .....	190
Register 3:	LDO Power Control (LDOPCTL), offset 0x034 .....	191
Register 4:	Raw Interrupt Status (RIS), offset 0x050 .....	192
Register 5:	Interrupt Mask Control (IMC), offset 0x054 .....	193
Register 6:	Masked Interrupt Status and Clear (MISC), offset 0x058 .....	194
Register 7:	Reset Cause (RESC), offset 0x05C .....	195
Register 8:	Run-Mode Clock Configuration (RCC), offset 0x060 .....	196
Register 9:	XTAL to PLL Translation (PLLCFG), offset 0x064 .....	200
Register 10:	GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C .....	201
Register 11:	Run-Mode Clock Configuration 2 (RCC2), offset 0x070 .....	203
Register 12:	Main Oscillator Control (MOSCCTL), offset 0x07C .....	205
Register 13:	Deep Sleep Clock Configuration (DSLPCLKCFG), offset 0x144 .....	206
Register 14:	Device Identification 1 (DID1), offset 0x004 .....	207
Register 15:	Device Capabilities 0 (DC0), offset 0x008 .....	209
Register 16:	Device Capabilities 1 (DC1), offset 0x010 .....	210
Register 17:	Device Capabilities 2 (DC2), offset 0x014 .....	212
Register 18:	Device Capabilities 3 (DC3), offset 0x018 .....	214

Register 19:	Device Capabilities 4 (DC4), offset 0x01C .....	216
Register 20:	Device Capabilities 5 (DC5), offset 0x020 .....	217
Register 21:	Device Capabilities 6 (DC6), offset 0x024 .....	219
Register 22:	Device Capabilities 7 (DC7), offset 0x028 .....	220
Register 23:	Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100 .....	222
Register 24:	Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110 .....	224
Register 25:	Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120 .....	226
Register 26:	Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104 .....	228
Register 27:	Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114 .....	231
Register 28:	Deep Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124 .....	234
Register 29:	Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108 .....	237
Register 30:	Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118 .....	239
Register 31:	Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128 .....	241
Register 32:	Software Reset Control 0 (SRCR0), offset 0x040 .....	243
Register 33:	Software Reset Control 1 (SRCR1), offset 0x044 .....	244
Register 34:	Software Reset Control 2 (SRCR2), offset 0x048 .....	246
<b>Hibernation Module</b> .....	<b>247</b>	
Register 1:	Hibernation RTC Counter (HIBRTCC), offset 0x000 .....	256
Register 2:	Hibernation RTC Match 0 (HIBRTCM0), offset 0x004 .....	257
Register 3:	Hibernation RTC Match 1 (HIBRTCM1), offset 0x008 .....	258
Register 4:	Hibernation RTC Load (HIBRTCLD), offset 0x00C .....	259
Register 5:	Hibernation Control (HIBCTL), offset 0x010 .....	260
Register 6:	Hibernation Interrupt Mask (HIBIM), offset 0x014 .....	263
Register 7:	Hibernation Raw Interrupt Status (HIBRIS), offset 0x018 .....	264
Register 8:	Hibernation Masked Interrupt Status (HIBMIS), offset 0x01C .....	265
Register 9:	Hibernation Interrupt Clear (HIBIC), offset 0x020 .....	266
Register 10:	Hibernation RTC Trim (HIBRTCT), offset 0x024 .....	267
Register 11:	Hibernation Data (HIBDATA), offset 0x030-0x12C .....	268
<b>Internal Memory</b> .....	<b>269</b>	
Register 1:	ROM Control (RMCTL), offset 0x0F0 .....	275
Register 2:	Flash Memory Address (FMA), offset 0x000 .....	276
Register 3:	Flash Memory Data (FMD), offset 0x004 .....	277
Register 4:	Flash Memory Control (FMC), offset 0x008 .....	278
Register 5:	Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C .....	280
Register 6:	Flash Controller Interrupt Mask (FCIM), offset 0x010 .....	281
Register 7:	Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014 .....	282
Register 8:	USec Reload (USECRL), offset 0x140 .....	284
Register 9:	Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200 .....	285
Register 10:	Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400 .....	286
Register 11:	User Debug (USER_DBG), offset 0x1D0 .....	287
Register 12:	User Register 0 (USER_REG0), offset 0x1E0 .....	288

Register 14:	User Register 2 (USER_REG2), offset 0x1E8 .....	290
Register 15:	User Register 3 (USER_REG3), offset 0x1EC .....	291
Register 16:	Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204 .....	292
Register 17:	Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208 .....	293
Register 18:	Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C .....	294
Register 19:	Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404 .....	295

Register 20:	Flash Memory Protection Program Enable 2 (FMPPE2), offset 0x408 .....	296
Register 21:	Flash Memory Protection Program Enable 3 (FMPPE3), offset 0x40C .....	297
<b>Micro Direct Memory Access (μDMA) .....</b>		<b>298</b>
Register 1:	DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000 .....	320
Register 2:	DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004 .....	321
Register 3:	DMA Channel Control Word (DMACHCTL), offset 0x008 .....	322
Register 4:	DMA Status (DMASTAT), offset 0x000 .....	326
Register 5:	DMA Configuration (DMACFG), offset 0x004 .....	328
Register 6:	DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008 .....	329
Register 7:	DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C .....	330
Register 8:	DMA Channel Wait on Request Status (DMAWAITSTAT), offset 0x010 .....	331
Register 9:	DMA Channel Software Request (DMASWREQ), offset 0x014 .....	332
Register 10:	DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018 .....	333
Register 11:	DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C .....	335
Register 12:	DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020 .....	336
Register 13:	DMA Channel Request Mask Clear (DMAREQMASKCLR), offset 0x024 .....	338
Register 14:	DMA Channel Enable Set (DMAENASET), offset 0x028 .....	339
Register 15:	DMA Channel Enable Clear (DMAENACLR), offset 0x02C .....	341
Register 16:	DMA Channel Primary Alternate Set (DMAALTSET), offset 0x030 .....	342
Register 17:	DMA Channel Primary Alternate Clear (DMAALTCLR), offset 0x034 .....	344
Register 18:	DMA Channel Priority Set (MAPRIOSET), offset 0x038 .....	345
Register 19:	DMA Channel Priority Clear (MAPRIOCLR), offset 0x03C .....	347
Register 20:	DMA Bus Error Clear (DMAERRCLR), offset 0x04C .....	348
Register 21:	DMA Peripheral Identification 0 (DMAPeriphID0), offset 0xFE0 .....	350
Register 22:	DMA Peripheral Identification 1 (DMAPeriphID1), offset 0xFE4 .....	351
Register 23:	DMA Peripheral Identification 2 (DMAPeriphID2), offset 0xFE8 .....	352
Register 24:	DMA Peripheral Identification 3 (DMAPeriphID3), offset 0xFEC .....	353
Register 25:	DMA Peripheral Identification 4 (DMAPeriphID4), offset 0xFD0 .....	354
Register 26:	DMA PrimeCell Identification 0 (MAPCellID0), offset 0xFF0 .....	355
Register 27:	DMA PrimeCell Identification 1 (MAPCellID1), offset 0xFF4 .....	356
Register 28:	DMA PrimeCell Identification 2 (MAPCellID2), offset 0xFF8 .....	357
Register 29:	DMA PrimeCell Identification 3 (MAPCellID3), offset 0xFFC .....	358
<b>General-Purpose Input/Outputs (GPIOs) .....</b>		<b>359</b>
Register 1:	GPIO Data (GPIODATA), offset 0x000 .....	368
Register 2:	GPIO Direction (GPIODIR), offset 0x400 .....	369
Register 3:	GPIO Interrupt Sense (GPIOIS), offset 0x404 .....	370
Register 4:	GPIO Interrupt Both Edges (GPIOIBE), offset 0x408 .....	371
Register 5:	GPIO Interrupt Event (GPIOEV), offset 0x40C .....	372
Register 6:	GPIO Interrupt Mask (GPIOIM), offset 0x410 .....	373
Register 7:	GPIO Raw Interrupt Status (PIORIS), offset 0x414 .....	374
Register 8:	GPIO Masked Interrupt Status (PIOMIS), offset 0x418 .....	375
Register 9:	GPIO Interrupt Clear (PIOICR), offset 0x41C .....	377
Register 10:	GPIO Alternate Function Select (GPIOAFSEL), offset 0x420 .....	378
Register 11:	GPIO 2-mA Drive Select (GPIODR2R), offset 0x500 .....	380
Register 12:	GPIO 4-mA Drive Select (GPIODR4R), offset 0x504 .....	381
Register 13:	GPIO 8-mA Drive Select (GPIODR8R), offset 0x508 .....	382
Register 14:	GPIO Open Drain Select (GPIOODR), offset 0x50C .....	383
Register 15:	GPIO Pull-Up Select (GPIOPUR), offset 0x510 .....	384

Register 16:	GPIO Pull-Down Select (GPIOPDR), offset 0x514 .....	386
Register 17:	GPIO Slew Rate Control Select (GPIOSLR), offset 0x518 .....	387
Register 18:	GPIO Digital Enable (GPIODEN), offset 0x51C .....	388
Register 19:	GPIO Lock (GPIOLOCK), offset 0x520 .....	390
Register 20:	GPIO Commit (GPIOCR), offset 0x524 .....	391
Register 21:	GPIO Analog Mode Select (GPIOAMSEL), offset 0x528 .....	393
Register 22:	GPIO Peripheral Identification 4 (GPIOPeriphID4), offset 0xFD0 .....	395
Register 23:	GPIO Peripheral Identification 5 (GPIOPeriphID5), offset 0xFD4 .....	396
Register 24:	GPIO Peripheral Identification 6 (GPIOPeriphID6), offset 0xFD8 .....	397
Register 25:	GPIO Peripheral Identification 7 (GPIOPeriphID7), offset 0xFDC .....	398
Register 26:	GPIO Peripheral Identification 0 (GPIOPeriphID0), offset 0xFE0 .....	399
Register 27:	GPIO Peripheral Identification 1 (GPIOPeriphID1), offset 0xFE4 .....	400
Register 28:	GPIO Peripheral Identification 2 (GPIOPeriphID2), offset 0xFE8 .....	401
Register 29:	GPIO Peripheral Identification 3 (GPIOPeriphID3), offset 0xFEC .....	402
Register 30:	GPIO PrimeCell Identification 0 (GPIOPCellID0), offset 0xFF0 .....	403
Register 31:	GPIO PrimeCell Identification 1 (GPIOPCellID1), offset 0xFF4 .....	404
Register 32:	GPIO PrimeCell Identification 2 (GPIOPCellID2), offset 0xFF8 .....	405
Register 33:	GPIO PrimeCell Identification 3 (GPIOPCellID3), offset 0xFFC .....	406
<b>General-Purpose Timers .....</b>	<b>407</b>	
Register 1:	GPTM Configuration (GPTMCFG), offset 0x000 .....	419
Register 2:	GPTM TimerA Mode (GPTMTAMR), offset 0x004 .....	420

# Revision History

The revision history table notes changes made between the indicated revisions of the LM3S3748 data sheet.

**Table 1. Revision History**

Date	Revision	Description
January 2011	9102	<ul style="list-style-type: none"><li>■ In <b>Application Interrupt and Reset Control (APINT)</b> register, changed bit name from <code>SYSRESETREQ</code> to <code>SYSRESREQ</code>.</li><li>■ Added <code>DEBUG</code> (Debug Priority) bit field to <b>System Handler Priority 3 (SYSPRI3)</b> register.</li><li>■ Added "Reset Sources" table to System Control chapter.</li><li>■ Removed mention of false-start bit detection in the UART chapter. This feature is not supported.</li><li>■ Added note that specific module clocks must be enabled before that module's registers can be programmed. There must be a delay of 3 system clocks after the module clock is enabled before any of that module's registers are accessed.</li><li>■ Changed I<sup>2</sup>C slave register base addresses and offsets to be relative to the I<sup>2</sup>C module base address of 0x4002.0000 and 0x4002.1000, so register bases and offsets were changed for all I<sup>2</sup>C slave registers. Note that the <code>hw_i2c.h</code> file in the StellarisWare Driver Library uses a base address of 0x4002.0800 and 0x4002.1800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that StellarisWare uses the old slave base address for these offsets.</li><li>■ Corrected nonlinearity and offset error parameters (<math>E_L</math>, <math>E_D</math> and <math>E_O</math>) in ADC Characteristics table.</li><li>■ Added specification for maximum input voltage on a non-power pin when the microcontroller is unpowered (<math>V_{NON}</math> parameter in Maximum Ratings table).</li><li>■ Additional minor data sheet clarifications and corrections.</li></ul>

**Table 1. Revision History (continued)**

Date	Revision	Description
September 2010	7783	<ul style="list-style-type: none"> <li>■ Reorganized ARM Cortex-M3 Processor Core, Memory Map and Interrupts chapters, creating two new chapters, The Cortex-M3 Processor and Cortex-M3 Peripherals. Much additional content was added, including all the Cortex-M3 registers.</li> <li>■ Changed register names to be consistent with StellarisWare® names: the Cortex-M3 <b>Interrupt Control and Status (ICSR)</b> register to the <b>Interrupt Control and State (INTCTRL)</b> register, and the Cortex-M3 <b>Interrupt Set Enable (SETNA)</b> register to the <b>Interrupt 0-31 Set Enable (EN0)</b> register.</li> <li>■ Clarified how reset operation affects the Hibernation module ("Register Reset" on page 254).</li> <li>■ In the Internal Memory chapter: <ul style="list-style-type: none"> <li>– Added clarification of instruction execution during Flash operations.</li> <li>– Deleted <b>ROM Version (RMVER)</b> register as it is not used.</li> </ul> </li> <li>■ In the GPIO chapter: <ul style="list-style-type: none"> <li>– Renamed the <b>GPIO High-Speed Control (GPIOHSCTL)</b> register to the <b>GPIO High-Performance Bus Control (GPIOHBCtl)</b> register.</li> <li>– Added clarification about the operation of the Advanced High-Performance Bus (AHB) and the legacy Advanced Peripheral Bus (APB).</li> <li>– Modified Figure 9-1 on page 360 and Figure 9-2 on page 361 to clarify operation of the GPIO inputs when used as an alternate function.</li> <li>– Corrected <b>GPIOAMSEL</b> bit field in <b>GPIO Analog Mode Select (GPIOAMSEL)</b> register to be eight-bits wide, bits[7:0].</li> </ul> </li> <li>■ In General-Purpose Timers chapter, clarified operation of the 32-bit RTC mode.</li> <li>■ Numerous improvements and clarifications to the USB chapter. Also corrected definitions for bits 2 and 5 in the <b>USBIE</b> register.</li> <li>■ In Electrical Characteristics chapter: <ul style="list-style-type: none"> <li>– Added "Input voltage for a GPIO configured as an analog input" value to Table 23-1 on page 810.</li> <li>– Added <math>I_{LKG}</math> parameter (GPIO input leakage current) to Table 23-4 on page 811.</li> <li>– Corrected values for <math>t_{CLKRF}</math> parameter (<math>SSIClk</math> rise/fall time) in Table 23-21 on page 821.</li> </ul> </li> <li>■ Added dimensions for Tray and Tape and Reel shipping mediums.</li> </ul>
June 2010	7403	<ul style="list-style-type: none"> <li>■ Corrected base address for SRAM in architectural overview chapter.</li> <li>■ Clarified system clock operation, adding content to "Clock Control" on page 178.</li> <li>■ In Signal Tables chapter, added table "Connections for Unused Signals."</li> <li>■ In "Reset Characteristics" table, corrected value for supply voltage (VDD) rise time.</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>
April 2010	7021	<ul style="list-style-type: none"> <li>■ Added caution note to the <b>I<sup>2</sup>C Master Timer Period (I2CMTPR)</b> register description and changed field width to 7 bits.</li> <li>■ Added note about <math>\overline{RST}</math> signal routing.</li> <li>■ Clarified the function of the <b>TnSTALL</b> bit in the <b>GPTMCTL</b> register.</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>

**Table 1. Revision History (continued)**

Date	Revision	Description
January 2010	6707	<ul style="list-style-type: none"> <li>■ In "System Control" section, clarified Debug Access Port operation after Sleep modes.</li> <li>■ Clarified wording on Flash memory access errors.</li> <li>■ Added section on Flash interrupts.</li> <li>■ Changed the reset value of the <b>ADC Sample Sequence Result FIFO n (ADCSSFIFOn)</b> registers to be indeterminate.</li> <li>■ Clarified operation of SSI transmit FIFO.</li> <li>■ Made these changes to the Operating Characteristics chapter: <ul style="list-style-type: none"> <li>– Added storage temperature ratings to "Temperature Characteristics" table</li> <li>– Added "ESD Absolute Maximum Ratings" table</li> </ul> </li> <li>■ Made these changes to the Electrical Characteristics chapter: <ul style="list-style-type: none"> <li>– In "Flash Memory Characteristics" table, corrected Mass erase time</li> <li>– Added sleep and deep-sleep wake-up times ("Sleep Modes AC Characteristics" table)</li> <li>– In "Reset Characteristics" table, corrected units for supply voltage (VDD) rise time</li> </ul> </li> </ul>
October 2009	6449	<ul style="list-style-type: none"> <li>■ Removed the MAXADCSPD bit field from the <b>DCGC0</b> register as it has no function in deep-sleep mode.</li> <li>■ Deleted reset value for 16-bit mode from <b>GPTMTAILR</b>, <b>GPTMTAMATCHR</b>, and <b>GPTMTAR</b> registers because the module resets in 32-bit mode.</li> <li>■ Corrected description for ADDR bit field in <b>USBTXFIFOSZ</b> and <b>USBRXFIFOSZ</b> registers.</li> <li>■ Clarified PWM source for ADC triggering</li> <li>■ Made these changes to the Electrical Characteristics chapter: <ul style="list-style-type: none"> <li>– Removed V<sub>SIH</sub> and V<sub>SIL</sub> parameters from Operating Conditions table.</li> <li>– Changed SSI set up and hold times to be expressed in system clocks, not ns.</li> <li>– Revised ADC electrical specifications to clarify, including reorganizing and adding new data.</li> <li>– Changed the name of the t<sub>HIB_REG_WRITE</sub> parameter to t<sub>HIB_REG_ACCESS</sub>.</li> <li>– Table added showing actual PLL frequency depending on input crystal.</li> </ul> </li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>

**Table 1. Revision History (continued)**

Date	Revision	Description
July 2009	5920	<ul style="list-style-type: none"> <li>■ Clarified Power-on reset and <code>RST</code> pin operation; added new diagrams.</li> <li>■ Corrected the reset value of the <b>Hibernation Data (HIBDATA)</b> and <b>Hibernation Control (HIBCTL)</b> registers.</li> <li>■ Clarified explanation of nonvolatile register programming in Internal Memory chapter.</li> <li>■ Added explanation of reset value to <b>FMPRE0/1/2/3</b>, <b>FMPPE0/1/2/3</b>, <b>USER_DBG</b>, and <b>USER_REG0/1</b> registers.</li> <li>■ Special bulk handling and packet splitting has never been supported as the μDMA module can support the same function. As a result, all references to these topics has been removed. Bit 7 in the <b>USBTXCSR<sub>n</sub></b> register only functions as NAKTO in Host mode and is reserved in Device mode. In addition, bit 0 in the <b>USBRXCSR<sub>n</sub></b> register is reserved.</li> <li>■ The <b>DISCON</b> and <b>CONN</b> bits in the <b>USBIS</b> and <b>USBIE</b> registers are not available in Device mode. When the USB controller is acting as a self-powered Device, a GPIO input or analog comparator input must be connected to VBUS and configured to generate an interrupt when the VBUS level drops. This interrupt is used to disable the pullup resistor on the <code>USB0DP</code> signal.</li> <li>■ Changed buffer type for <code>WAKE</code> pin to TTL.</li> <li>■ In ADC characteristics table, changed Max value for <code>GAIN</code> parameter from ±1 to ±3 and added <code>EIR</code>(Internal voltage reference error) parameter.</li> <li>■ Changed ordering numbers.</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>
April 2009	5368	<ul style="list-style-type: none"> <li>■ Added JTAG/SWD clarification (see “Communication with JTAG/SWD” on page 167).</li> <li>■ Added clarification that the PLL operates at 400 MHz, but is divided by two prior to the application of the output divisor.</li> <li>■ Corrected bits 2:1 in <b>I2CSIMR</b>, <b>I2CSRIS</b>, <b>I2CSMIS</b>, and <b>I2CSICR</b> registers to be reserved bits (cannot interrupt on start and stop conditions).</li> <li>■ Corrected bits 15:11 in <b>USBTXMAXP0/1/2</b> and <b>USBRXMAXP0/1/2</b> registers to be reserved bits (cannot define multiplier).</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>
January 2009	4724	<ul style="list-style-type: none"> <li>■ Corrected bit type for <b>RELOAD</b> bit field in SysTick Reload Value register; changed to R/W.</li> <li>■ Added clarification as to what happens when the SSI in slave mode is required to transmit but there is no data in the TX FIFO.</li> <li>■ Added section called "Setting the Device Address" for special considerations when writing the <b>USBFADDR</b> register.</li> <li>■ Corrected <b>USBEPIIDX</b> to be an 8-bit register.</li> <li>■ Added comparator operating mode tables.</li> <li>■ Corrected pin types of signals <code>RST</code> to "in" and <code>USB0RBIAS</code> to "out".</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul>
November 2008	4283	<ul style="list-style-type: none"> <li>■ Revised High-Level Block Diagram.</li> <li>■ Additional minor data sheet clarifications and corrections were made.</li> </ul>

**Table 1. Revision History (continued)**

Date	Revision	Description
October 2008	4149	<ul style="list-style-type: none"> <li>■ Added note on clearing interrupts to the Interrupts chapter:  <b>Note:</b> It may take several processor cycles after a write to clear an interrupt source in order for NVIC to see the interrupt source de-assert. This means if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer)</li> <li>■ Added clarification on JTAG reset to the JTAG chapter:            In order to reset the JTAG module after the device has been powered on, the <b>TMS</b> input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains.</li> <li>■ The binary value was incorrect in the JTAG 16-bit switch sequence in the JTAG-to-SWD Switching section in the JTAG chapter. Sentence changed to:            The 16-bit switch sequence for switching to JTAG mode is defined as b1110011100111100, transmitted LSB first.</li> <li>■ The <b>FMA</b> value for the <b>FMPRE3</b> register was incorrect in the Flash Resident Registers table in the Internal Memory chapter. The correct value is 0x0000.0006.</li> <li>■ Step 1 of the Initialization and Configuration procedure in the ADC chapter states the wrong register to use to enable the ADC clock. Sentence changed to:            1. Enable the ADC clock by writing a value of 0x0001.0000 to the <b>RCGC0</b> register.</li> <li>■ In the USB chapter, clarified endpoint terminology and added a new section on DMA Operation.</li> <li>■ Incorrect Comparator Operating Modes tables were removed from the Analog Comparators chapter.</li> <li>■ Additional minor data sheet clarifications and corrections were made.</li> </ul>
June 2008	2972	Started tracking revision history.

# About This Document

This data sheet provides reference information for the LM3S3748 microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M3 core.

## Audience

This manual is intended for system software developers, hardware designers, and application developers.

## About This Manual

This document is organized into sections that correspond to each major feature.

## Related Documents

The following related documents are available on the Stellaris® web site at [www.ti.com/stellaris](http://www.ti.com/stellaris):

- *Stellaris® Errata*

This documentation list was current as of publication date. Please check the web site for additional documentation, including application notes and white papers.

## Documentation Conventions

This document uses the conventions shown in Table 2 on page 34.

**Table 2. Documentation Conventions**

Notation	Meaning
<b>General Register Notation</b>	
<b>REGISTER</b>	APB registers are indicated in uppercase bold. For example, <b>PBORCTL</b> is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, <b>SRCRn</b> represents any (or all) of the three Software Reset Control registers: <b>SRCR0</b> , <b>SRCR1</b> , and <b>SRCR2</b> .
bit	A single bit in a register.
bit field	Two or more consecutive and related bits.
offset 0xnnnn	A hexadecimal increment to a register's address, relative to that module's base address as specified in Table 2-4 on page 74.
Register N	Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.
reserved	Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
yy:xx	The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.
<b>Register Bit/Field Types</b>	This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.
RC	Software can read this field. The bit or field is cleared by hardware after reading the bit/field.
RO	Software can read this field. Always write the chip reset value.
R/W	Software can read or write this field.
R/WC	Software can read or write this field. Writing to it with any value clears the register.
R/W1C	Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read.
R/W1S	Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.
W1C	Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.
WO	Only a write by software is valid; a read of the register returns no meaningful data.
<b>Register Bit/Field Reset Value</b>	This value in the register bit diagram shows the bit/field value after any reset, unless noted.
0	Bit cleared to 0 on chip reset.
1	Bit set to 1 on chip reset.
-	Nondeterministic.
<b>Pin/Signal Notation</b>	
[]	Pin alternate function; a pin defaults to the signal without the brackets.
pin	Refers to the physical connection on the package.
signal	Refers to the electrical signal encoding of a pin.

**Table 2. Documentation Conventions (continued)**

Notation	Meaning
assert a signal	Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see SIGNAL and <u>SIGNAL</u> below).
deassert a signal	Change the value of the signal from the logically True state to the logically False state.
<u>SIGNAL</u>	Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert <u>SIGNAL</u> is to drive it Low; to deassert <u>SIGNAL</u> is to drive it High.
SIGNAL	Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert SIGNAL is to drive it High; to deassert SIGNAL is to drive it Low.
<b>Numbers</b>	
X	An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.
0x	Hexadecimal numbers have a prefix of 0x. For example, 0x0FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.

# 1 Architectural Overview

The Stellaris® family of microcontrollers—the first ARM® Cortex™-M3 based controllers—brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications. These pioneering parts deliver customers 32-bit performance at a cost equivalent to legacy 8- and 16-bit devices, all in a package with a small footprint.

The Stellaris family offers efficient performance and extensive integration, favorably positioning the device into cost-conscious applications requiring significant control-processing and connectivity capabilities. The Stellaris LM3S3000 series provides the industry's first ARM® Cortex™-M3 microcontrollers with USB 2.0 Full-Speed On-The-Go/Host/Device combinations.

The LM3S3748 microcontroller is targeted for industrial applications, including remote monitoring, electronic point-of-sale machines, test and measurement equipment, network appliances and switches, factory automation, HVAC and building control, gaming equipment, motion control, medical instrumentation, and fire and security.

For applications requiring extreme conservation of power, the LM3S3748 microcontroller features a battery-backed Hibernation module to efficiently power down the LM3S3748 to a low-power state during extended periods of inactivity. With a power-up/power-down sequencer, a continuous time counter (RTC), a pair of match registers, an APB interface to the system bus, and dedicated non-volatile memory, the Hibernation module positions the LM3S3748 microcontroller perfectly for battery applications.

In addition, the LM3S3748 microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM3S3748 microcontroller is code-compatible to all members of the extensive Stellaris family; providing flexibility to fit our customers' precise needs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network. See "Ordering and Contact Information" on page 876 for ordering information for Stellaris family devices.

## 1.1 Product Features

The LM3S3748 microcontroller includes the following product features:

- 32-Bit RISC Performance
  - 32-bit ARM® Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
  - System timer (SysTick), providing a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism
  - Thumb®-compatible Thumb-2-only instruction set processor core for high code density
  - 50-MHz operation
  - Hardware-division and single-cycle-multiplication

- Integrated Nested Vectored Interrupt Controller (NVIC) providing deterministic interrupt handling
  - 41 interrupts with eight priority levels
  - Memory protection unit (MPU), providing a privileged mode for protected operating system functionality
  - Unaligned data access, enabling data to be efficiently packed into memory
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
- ARM® Cortex™-M3 Processor Core
    - Compact core.
    - Thumb-2 instruction set, delivering the high-performance expected of an ARM core in the memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller class applications.
    - Rapid application execution through Harvard architecture characterized by separate buses for instruction and data.
    - Exceptional interrupt handling, by implementing the register manipulations required for handling an interrupt in hardware.
    - Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
    - External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications.
    - Memory protection unit (MPU) to provide a privileged mode of operation for complex applications.
    - Migration from the ARM7™ processor family for better performance and power efficiency.
    - Full-featured debug solution
      - Serial Wire JTAG Debug Port (SWJ-DP)
      - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
      - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
      - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
      - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer
    - Optimized for single-cycle flash usage
    - Three sleep modes with clock gating for low power
    - Single-cycle multiply instruction and hardware divide

- Atomic operations
- ARM Thumb2 mixed 16-/32-bit instruction set
- 1.25 DMIPS/MHz
- JTAG
  - IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
  - Four-bit Instruction Register (IR) chain for storing JTAG instructions
  - IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTEST
  - ARM additional instructions: APACC, DPACC and ABORT
  - Integrated ARM Serial Wire Debug (SWD)
- Hibernation
  - System power control using discrete external regulator
  - Dedicated pin for waking from an external signal
  - Low-battery detection, signaling, and interrupt generation
  - 32-bit real-time clock (RTC)
  - Two 32-bit RTC match registers for timed wake-up and interrupt generation
  - Clock source from a 32.768-kHz external oscillator or a 4.194304-MHz crystal
  - RTC predivider trim for making fine adjustments to the clock rate
  - 64 32-bit words of non-volatile memory
  - Programmable interrupts for RTC match, external wake, and low battery events
- Internal Memory
  - 128 KB single-cycle flash
    - User-managed flash block protection on a 2-KB block basis
    - User-managed flash data programming
    - User-defined and managed flash-protection block
  - 64 KB single-cycle SRAM
  - Pre-programmed ROM
    - Stellaris family peripheral driver library (DriverLib)
    - Stellaris boot loader
- DMA Controller

- ARM PrimeCell® 32-channel configurable µDMA controller
  - Support for multiple transfer modes
    - Basic, for simple transfer scenarios
    - Ping-pong, for continuous data flow to/from peripherals
    - Scatter-gather, from a programmable list of arbitrary transfers initiated from a single request
  - Dedicated channels for supported peripherals
  - One channel each for receive and transmit path for bidirectional peripherals
  - Dedicated channel for software-initiated transfers
  - Independently configured and operated channels
  - Per-channel configurable bus arbitration scheme
  - Two levels of priority
  - Design optimizations for improved bus access performance between µDMA controller and the processor core
    - µDMA controller access is subordinate to core access
    - RAM striping
    - Peripheral bus segmentation
  - Data sizes of 8, 16, and 32 bits
  - Source and destination address increment size of byte, half-word, word, or no increment
  - Maskable device requests
  - Optional software initiated requests for any channel
  - Interrupt on transfer completion, with a separate interrupt per channel
- GPIOs
- 3-61 GPIOs, depending on configuration
  - 5-V-tolerant in input configuration
  - Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code
  - Programmable control for GPIO interrupts
    - Interrupt generation masking
    - Edge-triggered on rising, falling, or both

- Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can initiate an ADC sample sequence
- Pins configured as digital inputs are Schmitt-triggered.
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
  - Slew rate control for the 8-mA drive
  - Open drain enables
  - Digital input enables
- General-Purpose Timers
  - Four General-Purpose Timer Modules (GPTM), each of which provides two 16-bit timers/counters. Each GPTM can be configured to operate independently:
    - As a single 32-bit timer
    - As one 32-bit Real-Time Clock (RTC) to event capture
    - For Pulse Width Modulation (PWM)
    - To trigger analog-to-digital conversions
  - 32-bit Timer modes
    - Programmable one-shot timer
    - Programmable periodic timer
    - Real-Time Clock when using an external 32.768-KHz clock as the input
    - User-enabled stalling when the controller asserts CPU Halt flag during debug
    - ADC event trigger
  - 16-bit Timer modes
    - General-purpose timer function with an 8-bit prescaler (for one-shot and periodic modes only)
    - Programmable one-shot timer
    - Programmable periodic timer
    - User-enabled stalling when the controller asserts CPU Halt flag during debug

- ADC event trigger
- 16-bit Input Capture modes
  - Input edge count capture
  - Input edge time capture
- 16-bit PWM mode
  - Simple PWM mode with software-programmable output inversion of the PWM signal
- ARM FiRM-compliant Watchdog Timer
  - 32-bit down counter with a programmable load register
  - Separate watchdog clock with an enable
  - Programmable interrupt generation logic with interrupt masking
  - Lock register protection from runaway software
  - Reset generation logic with an enable/disable
  - User-enabled stalling when the controller asserts the CPU Halt flag during debug
- ADC
  - Eight analog input channels
  - Single-ended and differential-input configurations
  - On-chip internal temperature sensor
  - Sample rate of one million samples/second
  - Flexible, configurable analog-to-digital conversion
  - Four programmable sample conversion sequences from one to eight entries long, with corresponding conversion result FIFOs
  - Flexible trigger control
    - Controller (software)
    - Timers
    - Analog Comparators
    - PWM
    - GPIO
  - Hardware averaging of up to 64 samples for improved accuracy
  - Converter uses an internal 3-V reference

- Power and ground for the analog circuitry is separate from the digital power and ground
- **UART**
  - Two fully programmable 16C550-type UARTs with IrDA support
  - Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
  - Programmable baud-rate generator allowing speeds up to 3.125 Mbps
  - Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
  - FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
  - Standard asynchronous communication bits for start, stop, and parity
  - Line-break generation and detection
  - Fully programmable serial interface characteristics
    - 5, 6, 7, or 8 data bits
    - Even, odd, stick, or no-parity bit generation/detection
    - 1 or 2 stop bit generation
  - IrDA serial-IR (SIR) encoder/decoder providing
    - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
    - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
    - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
    - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
  - Dedicated Direct Memory Access (DMA) transmit and receive channels
- **Synchronous Serial Interface (SSI)**
  - Two SSI modules, each with the following features:
    - Master or slave operation
    - Support for Direct Memory Access (DMA)
    - Programmable clock bit rate and prescale
    - Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
    - Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
    - Programmable data frame size from 4 to 16 bits

- Internal loopback test mode for diagnostic/debug testing
- I<sup>2</sup>C
  - Two I<sup>2</sup>C modules, each with the following features:
    - Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
      - Supports both sending and receiving data as either a master or a slave
      - Supports simultaneous master and slave operation
    - Four I<sup>2</sup>C modes
      - Master transmit
      - Master receive
      - Slave transmit
      - Slave receive
    - Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
    - Master and slave interrupt generation
      - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
      - Slave generates interrupts when data has been sent or requested by a master
    - Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- USB
  - Standards-based
  - USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation
  - USB Device or Host mode
  - Integrated PHY
  - 4 transfer types: Control, Interrupt, Bulk, and Isochronous
  - 8 endpoints
    - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
    - 3 configurable IN endpoints and 3 configurable OUT endpoints
  - 2 KB dedicated endpoint memory
    - Direct memory access (DMA)
    - One endpoint may be defined for double-buffered 1023-byte isochronous packet size

- Analog Comparators
  - Two independent integrated analog comparators
  - Configurable for output to drive an output pin, generate an interrupt, or initiate an ADC sample sequence
  - Compare external pin input to external pin input or to internal programmable voltage reference
  - Compare a test voltage against any one of these voltages
    - An individual external reference voltage
    - A shared single external reference voltage
    - A shared internal reference voltage
- PWM
  - Four PWM generator blocks, each with one 16-bit counter, two PWM comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector
  - Four fault inputs in hardware to promote low-latency shutdown
  - One 16-bit counter
    - Runs in Down or Up/Down mode
    - Output frequency controlled by a 16-bit load value
    - Load value updates can be synchronized
    - Produces output signals at zero and load value
  - Two PWM comparators
    - Comparator value updates can be synchronized
    - Produces output signals on match
  - PWM generator
    - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
    - Produces two independent PWM signals
  - Dead-band generator
    - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
    - Can be bypassed, leaving input PWM signals unmodified
  - Flexible output control block with PWM output enable of each PWM signal
    - PWM output enable of each PWM signal

- Optional output inversion of each PWM signal (polarity control)
  - Optional fault handling for each PWM signal
  - Synchronization of timers in the PWM generator blocks
  - Synchronization of timer/comparator updates across the PWM generator blocks
  - Interrupt status summary of the PWM generator blocks
  - Can initiate an ADC sample sequence
- QEI
    - Position integrator that tracks the encoder position
    - Velocity capture using built-in timer
    - The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
    - Interrupt generation on:
      - Index pulse
      - Velocity-timer expiration
      - Direction change
      - Quadrature error detection
- Power
    - On-chip Low Drop-Out (LDO) voltage regulator, with programmable output user-adjustable from 2.25 V to 2.75 V
    - Hibernation module handles the power-up/down 3.3 V sequencing and control for the core digital logic and analog circuits
    - Low-power options on controller: Sleep and Deep-sleep modes
    - Low-power options for peripherals: software controls shutdown of individual peripherals
    - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Flexible Reset Sources
    - Power-on reset (POR)
    - Reset pin assertion
    - Brown-out (BOR) detector alerts to system power drops
    - Software reset
    - Watchdog timer reset

- Internal low drop-out (LDO) regulator output goes unregulated
- Industrial temperature 100-pin RoHS-compliant LQFP package

## **1.2 Target Applications**

- Remote monitoring
- Electronic point-of-sale (POS) machines
- Test and measurement equipment
- Network appliances and switches
- Factory automation
- HVAC and building control
- Gaming equipment
- Motion control
- Medical instrumentation
- Fire and security
- Power and energy
- Transportation

## **1.3 High-Level Block Diagram**

Figure 1-1 on page 47 depicts the features on the Stellaris LM3S3748 microcontroller.

**Figure 1-1. Stellaris LM3S3748 Microcontroller High-Level Block Diagram**

## 1.4 Functional Overview

The following sections provide an overview of the features of the LM3S3748 microcontroller. The page number in parenthesis indicates where that feature is discussed in detail. Ordering and support information can be found in “Ordering and Contact Information” on page 876.

### 1.4.1 ARM Cortex™-M3

#### 1.4.1.1 Processor Core (see page 55)

All members of the Stellaris product family, including the LM3S3748 microcontroller, are designed around an ARM Cortex™-M3 processor core. The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low-power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

#### 1.4.1.2 Memory Map (see page 74)

A memory map lists the location of instructions and data in memory. The memory map for the LM3S3748 controller can be found in Table 2-4 on page 74. Register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map.

#### 1.4.1.3 System Timer (SysTick) (see page 97)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter. Software can use this to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

#### 1.4.1.4 Nested Vectored Interrupt Controller (NVIC) (see page 98)

The LM3S3748 controller includes the ARM Nested Vectored Interrupt Controller (NVIC) on the ARM® Cortex™-M3 core. The NVIC and Cortex-M3 prioritize and handle all exceptions. All exceptions are handled in Handler Mode. The processor state is automatically stored to the stack on an exception, and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, which enables efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 41 interrupts.

#### **1.4.1.5 System Control Block (SCB) (see page 100)**

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

#### **1.4.1.6 Memory Protection Unit (MPU) (see page 100)**

The MPU supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

#### **1.4.1.7 Direct Memory Access (see page 298)**

The LM3S3748 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the expanded available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported peripheral and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller also supports sophisticated transfer modes such as ping-pong and scatter-gather, which allows the processor to set up a list of transfer tasks for the controller.

### **1.4.2 Motor Control Peripherals**

To enhance motor control, the LM3S3748 controller features Pulse Width Modulation (PWM) outputs and the Quadrature Encoder Interface (QEI).

#### **1.4.2.1 PWM**

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

On the LM3S3748, PWM motion control functionality can be achieved through:

- Dedicated, flexible motion control hardware using the PWM pins
- The motion control features of the general-purpose timers using the CCP pins

#### **PWM Pins (see page 725)**

The LM3S3748 PWM module consists of four PWM generator blocks and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins.

#### **CCP Pins (see page 413)**

The General-Purpose Timer Module's CCP (Capture Compare PWM) pins are software programmable to support a simple PWM mode with a software-programmable output inversion of the PWM signal.

**Fault Pins (see page 731)**

The LM3S3748 PWM module includes four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled.

**1.4.2.2 QEI (see page 776)**

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The Stellaris quadrature encoder with index (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

**1.4.3 Analog Peripherals**

To handle analog signals, the LM3S3748 microcontroller offers an Analog-to-Digital Converter (ADC).

For support of analog signals, the LM3S3748 microcontroller offers two analog comparators.

**1.4.3.1 ADC (see page 465)**

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number.

The LM3S3748 ADC module features 10-bit conversion resolution and supports eight input channels, plus an internal temperature sensor. Four buffered sample sequences allow rapid sampling of up to eight analog input sources without controller intervention. Each sample sequence provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequence priority.

**1.4.3.2 Analog Comparators (see page 713)**

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

The LM3S3748 microcontroller provides two independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

A comparator can compare a test voltage against any one of these voltages:

- An individual external reference voltage
- A shared single external reference voltage
- A shared internal reference voltage

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

## 1.4.4 Serial Communications Peripherals

The LM3S3748 controller supports both asynchronous and synchronous serial communications with:

- Two fully programmable 16C550-type UARTs
- Two SSI modules
- Two I<sup>2</sup>C modules
- One USB 2.0 full-speed controller

### 1.4.4.1 **UART (see page 500)**

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM3S3748 controller includes two fully programmable 16C550-type UARTs that support data transfer speeds up to 3.125 Mbps. (Although similar in functionality to a 16C550 UART, it is not register-compatible.) In addition, each UART is capable of supporting IrDA.

Separate 16x8 transmit (TX) and receive (RX) FIFOs reduce CPU interrupt service loading. The UART can generate individually masked interrupts from the RX, TX, modem status, and error conditions. The module provides a single combined interrupt when any of the interrupts are asserted and are unmasked.

### 1.4.4.2 **SSI (see page 543)**

Synchronous Serial Interface (SSI) is a four-wire bi-directional full and low-speed communications interface.

The LM3S3748 controller includes two SSI modules that provide the functionality for synchronous serial communications with peripheral devices, and can be configured to use the Freescale SPI, MICROWIRE, or TI synchronous serial interface frame formats. The size of the data frame is also configurable, and can be set between 4 and 16 bits, inclusive.

Each SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The TX and RX paths are buffered with internal FIFOs, allowing up to eight 16-bit values to be stored independently.

Each SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices.

Each SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

### 1.4.4.3 **I<sup>2</sup>C (see page 583)**

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL).

The I<sup>2</sup>C bus interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

The LM3S3748 controller includes two I<sup>2</sup>C modules that provide the ability to communicate to other IC devices over an I<sup>2</sup>C bus. The I<sup>2</sup>C bus supports devices that can both transmit and receive (write and read) data.

Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave. Each I<sup>2</sup>C module supports both sending and receiving data as either a master or a slave, and also supports the simultaneous operation as both a master and a slave. The four I<sup>2</sup>C modes are: Master Transmit, Master Receive, Slave Transmit, and Slave Receive.

A Stellaris I<sup>2</sup>C module can operate at two speeds: Standard (100 Kbps) and Fast (400 Kbps).

Both the I<sup>2</sup>C master and slave can generate interrupts. The I<sup>2</sup>C master generates interrupts when a transmit or receive operation completes (or aborts due to an error). The I<sup>2</sup>C slave generates interrupts when data has been sent or requested by a master.

#### **1.4.4.4 USB (see page 619)**

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The LM3S3748 controller supports the USB 2.0 full-speed configuration with Device or USB Host mode. The specified throughput for a USB 2.0 full-speed controller is 12 Mbps.

### **1.4.5 System Peripherals**

#### **1.4.5.1 Programmable GPIOs (see page 359)**

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections.

The Stellaris GPIO module is comprised of eight physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 3-61 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 794 for the signals available to each GPIO pin).

The GPIO module features programmable interrupt generation as either edge-triggered or level-sensitive on all pins, programmable control for GPIO pad configuration, and bit masking in both read and write operations through address lines. Pins configured as digital inputs are Schmitt-triggered.

#### **1.4.5.2 Four Programmable Timers (see page 407)**

Programmable timers can be used to count or time external events that drive the Timer input pins.

The Stellaris General-Purpose Timer Module (GPTM) contains four GPTM blocks. Each GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

When configured in 32-bit mode, a timer can run as a Real-Time Clock (RTC), one-shot timer or periodic timer. When in 16-bit mode, a timer can run as a one-shot timer or periodic timer, and can extend its precision by using an 8-bit prescaler. A 16-bit timer can also be configured for event capture or Pulse Width Modulation (PWM) generation.

### 1.4.5.3 Watchdog Timer (see page 441)

A watchdog timer can generate an interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way.

The Stellaris Watchdog Timer module consists of a 32-bit down counter, a programmable load register, interrupt generation logic, and a locking register.

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 1.4.6 Memory Peripherals

The LM3S3748 controller offers both single-cycle SRAM and single-cycle Flash memory.

### 1.4.6.1 SRAM (see page 269)

The LM3S3748 static random access memory (SRAM) controller supports 64 KB SRAM. The internal SRAM of the Stellaris devices starts at base address 0x2000.0000 of the device memory map. To reduce the number of time-consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the new Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

### 1.4.6.2 Flash (see page 270)

The LM3S3748 Flash controller supports 128 KB of flash memory. The flash is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

### 1.4.6.3 ROM (see page 830)

The LM3S3748 microcontroller ships with the Stellaris family Peripheral Driver Library conveniently preprogrammed in read-only memory (ROM). The Stellaris Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals, and includes a boot-loader capability. The library performs both peripheral initialization and peripheral control functions, with a choice of polled or interrupt-driven peripheral support, and takes full advantage of the stellar interrupt performance of the ARM® Cortex™-M3 core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free Stellaris boot loader included in the Stellaris Peripheral Driver Library can act as an application loader and support in-field firmware updates.

## 1.4.7 Additional Features

### 1.4.7.1 JTAG TAP Controller (see page 161)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing

information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is composed of the standard four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Stellaris JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core. This is implemented by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Stellaris JTAG instructions select the Stellaris TDO outputs. The multiplexer is controlled by the Stellaris JTAG controller, which has comprehensive programming for the ARM, Stellaris, and unimplemented JTAG instructions.

#### **1.4.7.2 System Control and Clocks (see page 173)**

System control determines the overall operation of the device. It provides information about the device, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

#### **1.4.7.3 Hibernation Module (see page 247)**

The Hibernation module provides logic to switch power off to the main processor and peripherals, and to wake on external or time-based events. The Hibernation module includes power-sequencing logic, a real-time clock with a pair of match registers, low-battery detection circuitry, and interrupt signalling to the processor. It also includes 64 32-bit words of non-volatile memory that can be used for saving state during hibernation.

### **1.4.8 Hardware Details**

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 793
- “Signal Tables” on page 794
- “Operating Characteristics” on page 809
- “Electrical Characteristics” on page 810
- “Package Information” on page 878

## 2 The Cortex-M3 Processor

The ARM® Cortex™-M3 processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- Compact core.
- Thumb-2 instruction set, delivering the high-performance expected of an ARM core in the memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller class applications.
- Rapid application execution through Harvard architecture characterized by separate buses for instruction and data.
- Exceptional interrupt handling, by implementing the register manipulations required for handling an interrupt in hardware.
- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications.
- Memory protection unit (MPU) to provide a privileged mode of operation for complex applications.
- Migration from the ARM7™ processor family for better performance and power efficiency.
- Full-featured debug solution
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer
- Optimized for single-cycle flash usage
- Three sleep modes with clock gating for low power
- Single-cycle multiply instruction and hardware divide
- Atomic operations
- ARM Thumb2 mixed 16-/32-bit instruction set
- 1.25 DMIPS/MHz

The Stellaris® family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motor control.

This chapter provides information on the Stellaris implementation of the Cortex-M3 processor, including the programming model, the memory model, the exception model, fault handling, and power management.

For technical details on the instruction set, see the *Cortex™-M3 Instruction Set Technical User's Manual*.

## 2.1 Block Diagram

The Cortex-M3 processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including single-cycle 32x32 multiplication and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M3 processor implements tightly coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M3 processor implements a version of the Thumb® instruction set, ensuring high code density and reduced program memory requirements. The Cortex-M3 instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M3 processor closely integrates a nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The Stellaris NVIC includes a non-maskable interrupt (NMI) and provides eight interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing interrupt latency. The hardware stacking of registers and the ability to suspend load-multiple and store-multiple operations further reduce interrupt latency. Interrupt handlers do not require any assembler stubs which removes code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another. To optimize low-power designs, the NVIC integrates with the sleep modes, including Deep-sleep mode, which enables the entire device to be rapidly powered down.

**Figure 2-1. CPU Block Diagram**

## 2.2 Overview

### 2.2.1 System-Level Interface

The Cortex-M3 processor provides multiple interfaces using AMBA® technology to provide high-speed, low-latency memory accesses. The core supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks, and thread-safe Boolean data handling.

The Cortex-M3 processor has a memory protection unit (MPU) that provides fine-grain memory control, enabling applications to implement security privilege levels and separate code, data and stack on a task-by-task basis.

### 2.2.2 Integrated Configurable Debug

The Cortex-M3 processor implements a complete hardware debug solution, providing high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The Stellaris implementation replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *ARM® Debug Interface V5 Architecture Specification* for details on SWJ-DP.

For system trace, the processor integrates an Instrumentation Trace Macrocell (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system trace events, a Serial Wire Viewer (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The Flash Patch and Breakpoint Unit (FPB) provides up to eight hardware breakpoint comparators that debuggers can use. The comparators in the FPB also provide remap functions of up to eight words in the program code in the CODE memory region. This enables applications stored in a read-only area of Flash memory to be patched in another area of on-chip SRAM or Flash memory. If a patch is required, the application programs the FPB to remap a number of addresses. When those addresses are accessed, the accesses are redirected to a remap table specified in the FPB configuration.

For more information on the Cortex-M3 debug capabilities, see the *ARM® Debug Interface V5 Architecture Specification*.

### 2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M3 trace data from the ITM, and an off-chip Trace Port Analyzer, as shown in Figure 2-2 on page 58.

**Figure 2-2. TPIU Block Diagram**

### 2.2.4 Cortex-M3 System Component Details

The Cortex-M3 includes the following system components:

- **SysTick**  
A 24-bit count-down timer that can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter (see “System Timer (SysTick)” on page 97).
- **Nested Vectored Interrupt Controller (NVIC)**  
An embedded interrupt controller that supports low latency interrupt processing (see “Nested Vectored Interrupt Controller (NVIC)” on page 98).
- **System Control Block (SCB)**

The programming model interface to the processor. The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions (see “System Control Block (SCB)” on page 100).

- Memory Protection Unit (MPU)

Improves system reliability by defining the memory attributes for different memory regions. The MPU provides up to eight different regions and an optional predefined background region (see “Memory Protection Unit (MPU)” on page 100).

## 2.3 Programming Model

This section describes the Cortex-M3 programming model. In addition to the individual core register descriptions, information about the processor modes and privilege levels for software execution and stacks is included.

### 2.3.1 Processor Mode and Privilege Levels for Software Execution

The Cortex-M3 has two modes of operation:

- Thread mode

Used to execute application software. The processor enters Thread mode when it comes out of reset.

- Handler mode

Used to handle exceptions. When the processor has finished exception processing, it returns to Thread mode.

In addition, the Cortex-M3 has two privilege levels:

- Unprivileged

In this mode, software has the following restrictions:

- Limited access to the `MSR` and `MRS` instructions and no use of the `CPS` instruction
- No access to the system timer, NVIC, or system control block
- Possibly restricted access to memory or peripherals

- Privileged

In this mode, software can use all the instructions and has access to all resources.

In Thread mode, the **CONTROL** register (see page 73) controls whether software execution is privileged or unprivileged. In Handler mode, software execution is always privileged.

Only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the `SVC` instruction to make a supervisor call to transfer control to privileged software.

### 2.3.2 Stacks

The processor uses a full descending stack, meaning that the stack pointer indicates the last stacked item on the stack memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements

two stacks: the main stack and the process stack, with independent copies of the stack pointer (see the **SP** register on page 63).

In Thread mode, the **CONTROL** register (see page 73) controls whether the processor uses the main stack or the process stack. In Handler mode, the processor always uses the main stack. The options for processor operations are shown in Table 2-1 on page 60.

**Table 2-1. Summary of Processor Mode, Privilege Level, and Stack Use**

Processor Mode	Use	Privilege Level	Stack Used
Thread	Applications	Privileged or unprivileged <sup>a</sup>	Main stack or process stack <sup>a</sup>
Handler	Exception handlers	Always privileged	Main stack

a. See **CONTROL** (page 73).

### 2.3.3 Register Map

Figure 2-3 on page 60 shows the Cortex-M3 register set. Table 2-2 on page 61 lists the Core registers. The core registers are not memory mapped and are accessed by register name, so the base address is n/a (not applicable) and there is no offset.

**Figure 2-3. Cortex-M3 Register Set**

**Table 2-2. Processor Register Map**

Offset	Name	Type	Reset	Description	See page
-	R0	R/W	-	Cortex General-Purpose Register 0	62
-	R1	R/W	-	Cortex General-Purpose Register 1	62
-	R2	R/W	-	Cortex General-Purpose Register 2	62
-	R3	R/W	-	Cortex General-Purpose Register 3	62
-	R4	R/W	-	Cortex General-Purpose Register 4	62
-	R5	R/W	-	Cortex General-Purpose Register 5	62
-	R6	R/W	-	Cortex General-Purpose Register 6	62
-	R7	R/W	-	Cortex General-Purpose Register 7	62
-	R8	R/W	-	Cortex General-Purpose Register 8	62
-	R9	R/W	-	Cortex General-Purpose Register 9	62
-	R10	R/W	-	Cortex General-Purpose Register 10	62
-	R11	R/W	-	Cortex General-Purpose Register 11	62
-	R12	R/W	-	Cortex General-Purpose Register 12	62
-	SP	R/W	-	Stack Pointer	63
-	LR	R/W	0xFFFF.FFFF	Link Register	64
-	PC	R/W	-	Program Counter	65
-	PSR	R/W	0x0100.0000	Program Status Register	66
-	PRIMASK	R/W	0x0000.0000	Priority Mask Register	70
-	FAULTMASK	R/W	0x0000.0000	Fault Mask Register	71
-	BASEPRI	R/W	0x0000.0000	Base Priority Mask Register	72
-	CONTROL	R/W	0x0000.0000	Control Register	73

### 2.3.4 Register Descriptions

This section lists and describes the Cortex-M3 registers, in the order shown in Figure 2-3 on page 60. The core registers are not memory mapped and are accessed by register name rather than offset.

**Note:** The register type shown in the register descriptions refers to type during program execution in Thread mode and Handler mode. Debug access can differ.

- Register 1: Cortex General-Purpose Register 0 (R0)**
- Register 2: Cortex General-Purpose Register 1 (R1)**
- Register 3: Cortex General-Purpose Register 2 (R2)**
- Register 4: Cortex General-Purpose Register 3 (R3)**
- Register 5: Cortex General-Purpose Register 4 (R4)**
- Register 6: Cortex General-Purpose Register 5 (R5)**
- Register 7: Cortex General-Purpose Register 6 (R6)**
- Register 8: Cortex General-Purpose Register 7 (R7)**
- Register 9: Cortex General-Purpose Register 8 (R8)**
- Register 10: Cortex General-Purpose Register 9 (R9)**
- Register 11: Cortex General-Purpose Register 10 (R10)**
- Register 12: Cortex General-Purpose Register 11 (R11)**
- Register 13: Cortex General-Purpose Register 12 (R12)**

The **Rn** registers are 32-bit general-purpose registers for data operations and can be accessed from either privileged or unprivileged mode.

#### Cortex General-Purpose Register 0 (R0)

Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	DATA	R/W	-	Register data.

## Register 14: Stack Pointer (SP)

The **Stack Pointer (SP)** is register R13. In Thread mode, the function of this register changes depending on the **ASP** bit in the **Control Register (CONTROL)** register. When the **ASP** bit is clear, this register is the **Main Stack Pointer (MSP)**. When the **ASP** bit is set, this register is the **Process Stack Pointer (PSP)**. On reset, the **ASP** bit is clear, and the processor loads the **MSP** with the value from address 0x0000.0000. The **MSP** can only be accessed in privileged mode; the **PSP** can be accessed in either privileged or unprivileged mode.

### Stack Pointer (SP)

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SP															
Type	R/W															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SP															
Type	R/W															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	SP	R/W	-	This field is the address of the stack pointer.
------	----	-----	---	---

## Register 15: Link Register (LR)

The **Link Register (LR)** is register R14, and it stores the return information for subroutines, function calls, and exceptions. **LR** can be accessed from either privileged or unprivileged mode.

`EXC_RETURN` is loaded into **LR** on exception entry. See Table 2-10 on page 90 for the values and description.

### Link Register (LR)

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	LINK	R/W	0xFFFF.FFFF	This field is the return address.

## Register 16: Program Counter (PC)

The **Program Counter (PC)** is register R15, and it contains the current program address. On reset, the processor loads the **PC** with the value of the reset vector, which is at address 0x0000.0004. Bit 0 of the reset vector is loaded into the **THUMB** bit of the **EPSR** at reset and must be 1. The **PC** register can be accessed in either privileged or unprivileged mode.

### Program Counter (PC)

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PC															
Type	R/W															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PC															
Type	R/W															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

#### Bit/Field                  Name                  Type                  Reset                  Description

31:0                  PC                  R/W                  -                  This field is the current program address.

## Register 17: Program Status Register (PSR)

**Note:** This register is also referred to as **xPSR**.

The **Program Status Register (PSR)** has three functions, and the register bits are assigned to the different functions:

- **Application Program Status Register (APSR)**, bits 31:27,
- **Execution Program Status Register (EPSR)**, bits 26:24, 15:10
- **Interrupt Program Status Register (IPSR)**, bits 6:0

The **PSR**, **IPSR**, and **EPSR** registers can only be accessed in privileged mode; the **APSR** register can be accessed in either privileged or unprivileged mode.

**APSR** contains the current state of the condition flags from previous instruction executions.

**EPSR** contains the Thumb state bit and the execution state bits for the If-Then (**IT**) instruction or the Interruptible-Continuable Instruction (**ICI**) field for an interrupted load multiple or store multiple instruction. Attempts to read the **EPSR** directly through application software using the **MSR** instruction always return zero. Attempts to write the **EPSR** using the **MSR** instruction in application software are always ignored. Fault handlers can examine the **EPSR** value in the stacked **PSR** to determine the operation that faulted (see “Exception Entry and Return” on page 88).

**IPSR** contains the exception type number of the current Interrupt Service Routine (ISR).

These registers can be accessed individually or as a combination of any two or all three registers, using the register name as an argument to the **MSR** or **MRS** instructions. For example, all of the registers can be read using **PSR** with the **MRS** instruction, or **APSR** only can be written to using **APSR** with the **MSR** instruction. page 66 shows the possible register combinations for the **PSR**. See the **MRS** and **MSR** instruction descriptions in the *Cortex™-M3 Instruction Set Technical User’s Manual* for more information about how to access the program status registers.

**Table 2-3. PSR Register Combinations**

Register	Type	Combination
<b>PSR</b>	R/W <sup>a, b</sup>	<b>APSR</b> , <b>EPSR</b> , and <b>IPSR</b>
<b>IEPSR</b>	RO	<b>EPSR</b> and <b>IPSR</b>
<b>IAPSR</b>	R/W <sup>a</sup>	<b>APSR</b> and <b>IPSR</b>
<b>EAPSR</b>	R/W <sup>b</sup>	<b>APSR</b> and <b>EPSR</b>

a. The processor ignores writes to the **IPSR** bits.

b. Reads of the **EPSR** bits return zero, and the processor ignores writes to these bits.

### Program Status Register (PSR)

Type R/W, reset 0x0100.0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28	V	R/W	0	<p><b>APSR</b> Overflow Flag</p> <p>Value Description</p> <p>1 The previous operation resulted in an overflow.</p> <p>0 The previous operation did not result in an overflow.</p> <p>The value of this bit is only meaningful when accessing <b>PSR</b> or <b>APSR</b>.</p>
27	Q	R/W	0	<p><b>APSR</b> DSP Overflow and Saturation Flag</p> <p>Value Description</p> <p>1 DSP Overflow or saturation has occurred.</p> <p>0 DSP overflow or saturation has not occurred since reset or since the bit was last cleared.</p> <p>The value of this bit is only meaningful when accessing <b>PSR</b> or <b>APSR</b>. This bit is cleared by software using an <b>MRS</b> instruction.</p>

Bit/Field	Name	Type	Reset	Description
26:25	ICI / IT	RO	0x0	<p><b>EPSR ICI / IT status</b></p> <p>These bits, along with bits 15:10, contain the Interruptible-Continuable Instruction (<b>ICI</b>) field for an interrupted load multiple or store multiple instruction or the execution state bits of the <b>IT</b> instruction.</p> <p>When <b>EPSR</b> holds the <b>ICI</b> execution state, bits 26:25 are zero.</p> <p>The If-Then block contains up to four instructions following a 16-bit <b>IT</b> instruction. Each instruction in the block is conditional. The conditions for the instructions are either all the same, or some can be the inverse of others. See the <i>Cortex™-M3 Instruction Set Technical User's Manual</i> for more information.</p> <p>The value of this field is only meaningful when accessing <b>PSR</b> or <b>EPSR</b>.</p>
24	THUMB	RO	1	<p><b>EPSR Thumb State</b></p> <p>This bit indicates the Thumb state and should always be set.</p> <p>The following can clear the <b>THUMB</b> bit:</p> <ul style="list-style-type: none"> <li>■ The <b>BLX</b>, <b>BX</b> and <b>POP{PC}</b> instructions</li> <li>■ Restoration from the stacked <b>xPSR</b> value on an exception return</li> <li>■ Bit 0 of the vector value on an exception entry</li> </ul> <p>Attempting to execute instructions when this bit is clear results in a fault or lockup. See "Lockup" on page 92 for more information.</p> <p>The value of this bit is only meaningful when accessing <b>PSR</b> or <b>EPSR</b>.</p>
23:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:10	ICI / IT	RO	0x0	<p><b>EPSR ICI / IT status</b></p> <p>These bits, along with bits 26:25, contain the Interruptible-Continuable Instruction (<b>ICI</b>) field for an interrupted load multiple or store multiple instruction or the execution state bits of the <b>IT</b> instruction.</p> <p>When an interrupt occurs during the execution of an <b>LDM</b>, <b>STM</b>, <b>PUSH</b> or <b>POP</b> instruction, the processor stops the load multiple or store multiple instruction operation temporarily and stores the next register operand in the multiple operation to bits 15:12. After servicing the interrupt, the processor returns to the register pointed to by bits 15:12 and resumes execution of the multiple load or store instruction. When <b>EPSR</b> holds the <b>ICI</b> execution state, bits 11:10 are zero.</p> <p>The If-Then block contains up to four instructions following a 16-bit <b>IT</b> instruction. Each instruction in the block is conditional. The conditions for the instructions are either all the same, or some can be the inverse of others. See the <i>Cortex™-M3 Instruction Set Technical User's Manual</i> for more information.</p> <p>The value of this field is only meaningful when accessing <b>PSR</b> or <b>EPSR</b>.</p>
9:7	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
6:0	ISRNUM	RO	0x00	<b>IPSR</b> ISR Number This field contains the exception type number of the current Interrupt Service Routine (ISR).
				Value      Description
			0x00	Thread mode
			0x01	Reserved
			0x02	NMI
			0x03	Hard fault
			0x04	Memory management fault
			0x05	Bus fault
			0x06	Usage fault
			0x07-0xA	Reserved
			0x0B	SVCALL
			0x0C	Reserved for Debug
			0x0D	Reserved
			0x0E	PendSV
			0x0F	SysTick
			0x10	Interrupt Vector 0
			0x11	Interrupt Vector 1
			...	...
			0x3F	Interrupt Vector 47
			0x40-0x7F	Reserved

See “Exception Types” on page 83 for more information.  
The value of this field is only meaningful when accessing **PSR** or **IPSR**.

## Register 18: Priority Mask Register (PRIMASK)

The **PRIMASK** register prevents activation of all exceptions with programmable priority. Reset, non-maskable interrupt (NMI), and hard fault are the only exceptions with fixed priority. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **PRIMASK** register, and the **CPS** instruction may be used to change the value of the **PRIMASK** register. See the *Cortex™-M3 Instruction Set Technical User's Manual* for more information on these instructions. For more information on exception priority levels, see "Exception Types" on page 83.

### Priority Mask Register (PRIMASK)

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															PRIMASK
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	PRIMASK	R/W	0	Priority Mask
		Value	Description	
		1	Prevents the activation of all exceptions with configurable priority.	
		0	No effect.	

## Register 19: Fault Mask Register (FAULTMASK)

The **FAULTMASK** register prevents activation of all exceptions except for the Non-Maskable Interrupt (NMI). Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **FAULTMASK** register, and the **CPS** instruction may be used to change the value of the **FAULTMASK** register. See the *Cortex™-M3 Instruction Set Technical User's Manual* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 83.

### Fault Mask Register (FAULTMASK)

Type R/W, reset 0x0000.0000

#### Bit/Field      Name      Type      Reset      Description

31:1      reserved      RO      0x0000.0000      Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0      FAULTMASK      R/W      0      Fault Mask

#### Value   Description

1      Prevents the activation of all exceptions except for NMI.

0      No effect.

The processor clears the FAULTMASK bit on exit from any exception handler except the NMI handler.

## Register 20: Base Priority Mask Register (BASEPRI)

The **BASEPRI** register defines the minimum priority for exception processing. When **BASEPRI** is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the **BASEPRI** value. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. For more information on exception priority levels, see “Exception Types” on page 83.

Base Priority Mask Register (BASEPRI)

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	BASEPRI	R/W	0x0	Base Priority Any exception that has a programmable priority level with the same or lower priority as the value of this field is masked. The <b>PRIMASK</b> register can be used to mask all exceptions with programmable priority levels. Higher priority exceptions have lower priority levels.
		Value	Description	
		0x0	All exceptions are unmasked.	
		0x1	All exceptions with priority level 1-7 are masked.	
		0x2	All exceptions with priority level 2-7 are masked.	
		0x3	All exceptions with priority level 3-7 are masked.	
		0x4	All exceptions with priority level 4-7 are masked.	
		0x5	All exceptions with priority level 5-7 are masked.	
		0x6	All exceptions with priority level 6-7 are masked.	
		0x7	All exceptions with priority level 7 are masked.	
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 21: Control Register (CONTROL)

The **CONTROL** register controls the stack used and the privilege level for software execution when the processor is in Thread mode. This register is only accessible in privileged mode.

Handler mode always uses **MSP**, so the processor ignores explicit writes to the **ASP** bit of the **CONTROL** register when in Handler mode. The exception entry and return mechanisms automatically update the **CONTROL** register based on the **EXC\_RETURN** value (see Table 2-10 on page 90). In an OS environment, threads running in Thread mode should use the process stack and the kernel and exception handlers should use the main stack. By default, Thread mode uses **MSP**. To switch the stack pointer used in Thread mode to **PSP**, either use the **MSR** instruction to set the **ASP** bit, as detailed in the *Cortex™-M3 Instruction Set Technical User's Manual*, or perform an exception return to Thread mode with the appropriate **EXC\_RETURN** value, as shown in Table 2-10 on page 90.

**Note:** When changing the stack pointer, software must use an **ISB** instruction immediately after the **MSR** instruction, ensuring that instructions after the **ISB** execute use the new stack pointer. See the *Cortex™-M3 Instruction Set Technical User's Manual*.

### Control Register (CONTROL)

Type R/W, reset 0x0000.0000

Value	Description									
1	Unprivileged software can be executed in Thread mode.									
0	Only privileged software can be executed in Thread mode.									

### 2.3.5 Exceptions and Interrupts

The Cortex-M3 processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See “Exception Entry and Return” on page 88 for more information.

The NVIC registers control interrupt handling. See “Nested Vectored Interrupt Controller (NVIC)” on page 98 for more information.

### 2.3.6 Data Types

The Cortex-M3 supports 32-bit words, 16-bit halfwords, and 8-bit bytes. The processor also supports 64-bit data transfer instructions. All instruction and data memory accesses are little endian. See “Memory Regions, Types and Attributes” on page 76 for more information.

## 2.4 Memory Model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The memory map for the LM3S3748 controller is provided in Table 2-4 on page 74. In this manual, register addresses are given as a hexadecimal increment, relative to the module’s base address as shown in the memory map.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data (see “Bit-Banding” on page 78).

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers (see “Cortex-M3 Peripherals” on page 97).

**Note:** Within the memory map, all reserved space returns a bus fault when read or written.

**Table 2-4. Memory Map**

Start	End	Description	For details, see page ...

### 2.4.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU split the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- Normal: The processor can re-order transactions for efficiency and perform speculative reads.
- Device: The processor preserves transaction order relative to other transactions to Device or Strongly Ordered memory.
- Strongly Ordered: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly Ordered memory mean that the memory system can buffer a write to Device memory but must not buffer a write to Strongly Ordered memory.

An additional memory attribute is Execute Never (XN), which means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

### 2.4.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing the order does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions (see “Software Ordering of Memory Accesses” on page 77).

However, the memory system does guarantee ordering of accesses to Device and Strongly Ordered memory. For two memory access instructions A1 and A2, if both A1 and A2 are accesses to either Device or Strongly Ordered memory, and if A1 occurs before A2 in program order, A1 is always observed before A2.

### 2.4.3 Behavior of Memory Accesses

Table 2-5 on page 77 shows the behavior of accesses to each region in the memory map. See “Memory Regions, Types and Attributes” on page 76 for more information on memory types and the XN attribute. Stellaris devices may have reserved memory areas within the address ranges shown below (refer to Table 2-4 on page 74 for more information).

**Table 2-5. Memory Access Behavior**

Address Range	Memory Region	Memory Type	Execute Never (XN)	Description
0x0000.0000 - 0x1FFF.FFFF	Code	Normal	-	This executable region is for program code. Data can also be stored here.
0x2000.0000 - 0x3FFF.FFFF	SRAM	Normal	-	This executable region is for data. Code can also be stored here. This region includes bit band and bit band alias areas (see Table 2-6 on page 79).
0x4000.0000 - 0x5FFF.FFFF	Peripheral	Device	XN	This region includes bit band and bit band alias areas (see Table 2-7 on page 79).
0x6000.0000 - 0x9FFF.FFFF	External RAM	Normal	-	This executable region is for data.
0xA000.0000 - 0xDFFF.FFFF	External device	Device	XN	This region is for external device memory.
0xE000.0000- 0xE00F.FFFF	Private peripheral bus	Strongly Ordered	XN	This region includes the NVIC, system timer, and system control block.
0xE010.0000- 0xFFFF.FFFF	Reserved	-	-	-

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region because the Cortex-M3 has separate buses that can perform instruction fetches and data accesses simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see “Memory Protection Unit (MPU)” on page 100.

The Cortex-M3 prefetches instructions ahead of execution and speculatively prefetches from branch target addresses.

### 2.4.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions for the following reasons:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces.
- Memory or devices in the memory map have different wait states.
- Some memory accesses are buffered or speculative.

“Memory System Ordering of Memory Accesses” on page 76 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The Cortex-M3 has the following memory barrier instructions:

- The Data Memory Barrier (`DMB`) instruction ensures that outstanding memory transactions complete before subsequent memory transactions.
- The Data Synchronization Barrier (`DSB`) instruction ensures that outstanding memory transactions complete before subsequent instructions execute.
- The Instruction Synchronization Barrier (`ISB`) instruction ensures that the effect of all completed memory transactions is recognizable by subsequent instructions.

Memory barrier instructions can be used in the following situations:

- MPU programming

- If the MPU settings are changed and the change must be effective on the very next instruction, use a `DSB` instruction to ensure the effect of the MPU takes place immediately at the end of context switching.
  - Use an `ISB` instruction to ensure the new MPU setting takes effect immediately after programming the MPU region or regions, if the MPU configuration code was accessed using a branch or call. If the MPU configuration code is entered using exception mechanisms, then an `ISB` instruction is not required.

- Vector table

If the program changes an entry in the vector table and then enables the corresponding exception, use a `DMB` instruction between the operations. The `DMB` instruction ensures that if the exception is taken immediately after being enabled, the processor uses the new exception vector.

- Self-modifying code

If a program contains self-modifying code, use an `ISB` instruction immediately after the code modification in the program. The `ISB` instruction ensures subsequent instruction execution uses the updated program.

- Memory map switching

If the system contains a memory map switching mechanism, use a `DSB` instruction after switching the memory map in the program. The `DSB` instruction ensures subsequent instruction execution uses the updated memory map.

- Dynamic exception priority change

When an exception priority has to change when the exception is pending or active, use `DSB` instructions after the change. The change then takes effect on completion of the `DSB` instruction.

Memory accesses to Strongly Ordered memory, such as the System Control Block, do not require the use of `DMB` instructions.

For more information on the memory barrier instructions, see the *Cortex™-M3 Instruction Set Technical User's Manual*.

## 2.4.5 Bit-Banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions. Accesses to the 32-MB SRAM alias region map to the 1-MB SRAM bit-band region, as shown in Table 2-6 on page 79. Accesses to the 32-MB peripheral alias region map to the 1-MB peripheral bit-band

region, as shown in Table 2-7 on page 79. For the specific address range of the bit-band regions, see Table 2-4 on page 74.

**Note:** A word access to the SRAM or the peripheral bit-band alias region maps to a single bit in the SRAM or peripheral bit-band region.

A word access to a bit band address results in a word access to the underlying memory, and similarly for halfword and byte accesses. This allows bit band accesses to match the access requirements of the underlying peripheral.

**Table 2-6. SRAM Memory Bit-Banding Regions**

Address Range	Memory Region	Instruction and Data Accesses
0x2000.0000 - 0x200F.FFFF	SRAM bit-band region	Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias.
0x2200.0000 - 0x23FF.FFFF	SRAM bit-band alias	Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped.

**Table 2-7. Peripheral Memory Bit-Banding Regions**

Address Range	Memory Region	Instruction and Data Accesses
0x4000.0000 - 0x400F.FFFF	Peripheral bit-band region	Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.
0x4200.0000 - 0x43FF.FFFF	Peripheral bit-band alias	Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted.

The following formula shows how the alias region maps onto the bit-band region:

`bit_word_offset = (byte_offset x 32) + (bit_number x 4)`

`bit_word_addr = bit_band_base + bit_word_offset`

where:

`bit_word_offset`

The position of the target bit in the bit-band memory region.

`bit_word_addr`

The address of the word in the alias memory region that maps to the targeted bit.

`bit_band_base`

The starting address of the alias region.

`byte_offset`

The number of the byte in the bit-band region that contains the targeted bit.

`bit_number`

The bit position, 0-7, of the targeted bit.

Figure 2-4 on page 80 shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FF.FFE0 maps to bit 0 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFE0 = 0x2200.0000 + (0x000F.FFFF * 32) + (0 * 4)$$

- The alias word at 0x23FF.FFFC maps to bit 7 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFFC = 0x2200.0000 + (0x000F.FFFF * 32) + (7 * 4)$$

- The alias word at 0x2200.0000 maps to bit 0 of the bit-band byte at 0x2000.0000:

$$0x2200.0000 = 0x2200.0000 + (0 * 32) + (0 * 4)$$

- The alias word at 0x2200.001C maps to bit 7 of the bit-band byte at 0x2000.0000:

$$0x2200.001C = 0x2200.0000 + (0 * 32) + (7 * 4)$$

**Figure 2-4. Bit-Band Mapping**

#### 2.4.5.1 Directly Accessing an Alias Region

Writing to a word in the alias region updates a single bit in the bit-band region.

Bit 0 of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit 0 set writes a 1 to the bit-band bit, and writing a value with bit 0 clear writes a 0 to the bit-band bit.

Bits 31:1 of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

When reading a word in the alias region, 0x0000.0000 indicates that the targeted bit in the bit-band region is clear and 0x0000.0001 indicates that the targeted bit in the bit-band region is set.

### 2.4.5.2 Directly Accessing a Bit-Band Region

"Behavior of Memory Accesses" on page 77 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

### 2.4.6 Data Storage

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. Data is stored in little-endian format, with the least-significant byte (lsbyte) of a word stored at the lowest-numbered byte, and the most-significant byte (msbyte) stored at the highest-numbered byte. Figure 2-5 on page 81 illustrates how data is stored.

**Figure 2-5. Data Storage**

### 2.4.7 Synchronization Primitives

The Cortex-M3 instruction set includes pairs of synchronization primitives which provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use these primitives to perform a guaranteed read-modify-write memory update sequence or for a semaphore mechanism.

A pair of synchronization primitives consists of:

- A Load-Exclusive instruction, which is used to read the value of a memory location and requests exclusive access to that location.
- A Store-Exclusive instruction, which is used to attempt to write to the same memory location and returns a status bit to a register. If this status bit is clear, it indicates that the thread or process gained exclusive access to the memory and the write succeeds; if this status bit is set, it indicates that the thread or process did not gain exclusive access to the memory and no write is performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions `LDREX` and `STREX`
- The halfword instructions `LDREXH` and `STREXH`
- The byte instructions `LDREXB` and `STREXB`

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform a guaranteed read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Update the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location, and test the returned status bit. If the status bit is clear, the read-modify-write completed successfully; if the status bit is set, no write was performed, which indicates that the value returned at step 1 might be out of date. The software must retry the read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphore as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded, then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M3 includes an exclusive access monitor that tags the fact that the processor has executed a Load-Exclusive instruction. The processor removes its exclusive access tag if:

- It executes a CLREX instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs, which means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see the *Cortex™-M3 Instruction Set Technical User's Manual*.

## 2.5 Exception Model

The ARM Cortex-M3 processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 2-8 on page 84 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 41 interrupts (listed in Table 2-9 on page 85).

Priorities on the system handlers are set with the NVIC **System Handler Priority n (SYSPRI<sub>n</sub>)** registers. Interrupts are enabled through the NVIC **Interrupt Set Enable n (EN<sub>n</sub>)** register and prioritized with the NVIC **Interrupt Priority n (PRI<sub>n</sub>)** registers. Priorities can be grouped by splitting priority levels into preemption priorities and subpriorities. All the interrupt registers are described in “Nested Vectored Interrupt Controller (NVIC)” on page 98.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

---

**Important:** After a write to clear an interrupt source, it may take several processor cycles for the NVIC to see the interrupt source de-assert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

---

See “Nested Vectored Interrupt Controller (NVIC)” on page 98 for more information on exceptions and interrupts.

### 2.5.1 Exception States

Each exception is in one of the following states:

- **Inactive.** The exception is not active and not pending.
  - **Pending.** The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
  - **Active.** An exception that is being serviced by the processor but has not completed.
- Note:** An exception handler can interrupt the execution of another exception handler. In this case, both exceptions are in the active state.
- **Active and Pending.** The exception is being serviced by the processor, and there is a pending exception from the same source.

### 2.5.2 Exception Types

The exception types are:

- **Reset.** Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI.** A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the **Interrupt Control and State (INTCTRL)** register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
- **Hard Fault.** A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory Management Fault.** A memory management fault is an exception that occurs because of a memory protection related fault, including access violation and no match. The MPU or the fixed memory protection constraints determine this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to Execute Never (XN) memory regions, even if the MPU is disabled.

- **Bus Fault.** A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.
- **Usage Fault.** A usage fault is an exception that occurs because of a fault related to instruction execution, such as:
  - An undefined instruction
  - An illegal unaligned access
  - Invalid state on instruction execution
  - An error on exception return
 An unaligned address on a word or halfword memory access or division by zero can cause a usage fault when the core is properly configured.
- **SVCALL.** A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.
- **Debug Monitor.** This exception is caused by the debug monitor (when not halting). This exception is only active when enabled. This exception does not activate if it is a lower priority than the current activation.
- **PendSV.** PendSV is a pendable, interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. PendSV is triggered using the **Interrupt Control and State (INTCTRL)** register.
- **SysTick.** A SysTick exception is an exception that the system timer generates when it reaches zero when it is enabled to generate an interrupt. Software can also generate a SysTick exception using the **Interrupt Control and State (INTCTRL)** register. In an OS environment, the processor can use this exception as system tick.
- **Interrupt (IRQ).** An interrupt, or IRQ, is an exception signaled by a peripheral or generated by a software request and fed through the NVIC (prioritized). All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. Table 2-9 on page 85 lists the interrupts on the LM3S3748 controller.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-8 on page 84 shows as having configurable priority (see the **SYSHNDCTRL** register on page 139 and the **DIS0** register on page 114).

For more information about hard faults, memory management faults, bus faults, and usage faults, see “Fault Handling” on page 90.

**Table 2-8. Exception Types**

Exception Type	Vector Number	Priority <sup>a</sup>	Vector Address or Offset <sup>b</sup>	Activation
-	0	-	0x0000.0000	Stack top is loaded from the first entry of the vector table on reset.
Reset	1	-3 (highest)	0x0000.0004	Asynchronous

**Table 2-8. Exception Types (continued)**

Exception Type	Vector Number	Priority <sup>a</sup>	Vector Address or Offset <sup>b</sup>	Activation
Non-Maskable Interrupt (NMI)	2	-2	0x0000.0008	Asynchronous
Hard Fault	3	-1	0x0000.000C	-
Memory Management	4	programmable <sup>c</sup>	0x0000.0010	Synchronous
Bus Fault	5	programmable <sup>c</sup>	0x0000.0014	Synchronous when precise and asynchronous when imprecise
Usage Fault	6	programmable <sup>c</sup>	0x0000.0018	Synchronous
-	7-10	-	-	Reserved
SVCall	11	programmable <sup>c</sup>	0x0000.002C	Synchronous
Debug Monitor	12	programmable <sup>c</sup>	0x0000.0030	Synchronous
-	13	-	-	Reserved
PendSV	14	programmable <sup>c</sup>	0x0000.0038	Asynchronous
SysTick	15	programmable <sup>c</sup>	0x0000.003C	Asynchronous
Interrupts	16 and above	programmable <sup>d</sup>	0x0000.0040 and above	Asynchronous

a. 0 is the default priority for all the programmable priorities.

b. See “Vector Table” on page 86.

c. See **SYSPRI1** on page 136.

d. See **PRIn** registers on page 122.

**Table 2-9. Interrupts**

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Vector Address or Offset	Description
0-15	-	0x0000.0000 - 0x0000.003C	Processor exceptions
16	0	0x0000.0040	GPIO Port A
17	1	0x0000.0044	GPIO Port B
18	2	0x0000.0048	GPIO Port C

### 2.5.3 Exception Handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs).** Interrupts (IRQx) are the exceptions handled by ISRs.
- **Fault Handlers.** Hard fault, memory management fault, usage fault, and bus fault are fault exceptions handled by the fault handlers.
- **System Handlers.** NMI, PendSV, SVCALL, SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.

### 2.5.4 Vector Table

The vector table contains the reset value of the stack pointer and the start addresses, also called exception vectors, for all exception handlers. The vector table is constructed using the vector address or offset shown in Table 2-8 on page 84. Figure 2-6 on page 87 shows the order of the exception

vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code

**Figure 2-6. Vector table**

Exception number	IRQ number	Offset	Vector
63	47	0x00FC	IRQ47
.	.	.	.
.	.	.	.
18	2	0x004C	IRQ2
17	1	0x0048	IRQ1
16	0	0x0044	IRQ0
15	-1	0x0040	Systick
14	-2	0x003C	PendSV
13		0x0038	Reserved
12			Reserved for Debug
11	-5	0x002C	SVCall
10			
9			Reserved
8			
7			
6	-10	0x0018	Usage fault
5	-11	0x0014	Bus fault
4	-12	0x0010	Memory management fault
3	-13	0x000C	Hard fault
2	-14	0x0008	NMI
1		0x0004	Reset
		0x0000	Initial SP value

On system reset, the vector table is fixed at address 0x0000.0000. Privileged software can write to the **Vector Table Offset (VTABLE)** register to relocate the vector table start address to a different memory location, in the range 0x0000.0100 to 0x3FFF.FF00 (see “Vector Table” on page 86). Note that when configuring the **VTABLE** register, the offset must be aligned on a 256-byte boundary.

## 2.5.5 Exception Priorities

As Table 2-8 on page 84 shows, all exceptions have an associated priority, with a lower priority value indicating a higher priority and configurable priorities for all exceptions except Reset, Hard fault, and NMI. If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities, see page 136 and page 122.

**Note:** Configurable priority values for the Stellaris implementation are in the range 0-7. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

## 2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This grouping divides each interrupt priority register entry into two fields:

- An upper field that defines the group priority
- A lower field that defines a subpriority within the group

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see page 130.

## 2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

- **Preemption.** When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See “Interrupt Priority Grouping” on page 88 for more information about preemption by an interrupt. When one exception preempts another, the exceptions are called nested exceptions. See “Exception Entry” on page 89 for more information.
- **Return.** Return occurs when the exception handler is completed, and there is no pending exception with sufficient priority to be serviced and the completed exception handler was not handling a late-arriving exception. The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See “Exception Return” on page 90 for more information.
- **Tail-Chaining.** This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.
- **Late-Arriving.** This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late

arrival because the state saved is the same for both exceptions. Therefore, the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

### 2.5.7.1 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either the processor is in Thread mode or the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers (see **PRIMASK** on page 70, **FAULTMASK** on page 71, and **BASEPRI** on page 72). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as *stacking* and the structure of eight data words is referred to as *stack frame*.

**Figure 2-7. Exception Stack Frame**

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame. Unless stack alignment is disabled, the stack frame is aligned to a double-word address. If the **STKALIGN** bit of the **Configuration Control (CCR)** register is set, stack align adjustment is performed during stacking.

The stack frame includes the return address, which is the address of the next instruction in the interrupted program. This value is restored to the **PC** at exception return so that the interrupted program resumes.

In parallel to the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an **EXC\_RETURN** value to the **LR**, indicating which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher-priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher-priority exception occurs during exception entry, known as late arrival, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception.

### 2.5.7.2 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the EXC\_RETURN value into the **PC**:

- An **LDM** or **POP** instruction that loads the **PC**
- A **BX** instruction using any register
- An **LDR** instruction with the **PC** as the destination

**EXC\_RETURN** is the value loaded into the **LR** on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest four bits of this value provide information on the return stack and processor mode. Table 2-10 on page 90 shows the EXC\_RETURN values with a description of the exception return behavior.

**EXC\_RETURN** bits 31:4 are all set. When this value is loaded into the **PC**, it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

**Table 2-10. Exception Return Behavior**

<b>EXC_RETURN[31:0]</b>	<b>Description</b>
0xFFFF.FFF0	Reserved
0xFFFF.FFF1	Return to Handler mode. Exception return uses state from <b>MSP</b> . Execution uses <b>MSP</b> after return.
0xFFFF.FFF2 - 0xFFFF.FFF8	Reserved
0xFFFF.FFF9	Return to Thread mode. Exception return uses state from <b>MSP</b> . Execution uses <b>MSP</b> after return.
0xFFFF.FFFA - 0xFFFF.FFFC	Reserved
0xFFFF.FFFD	Return to Thread mode. Exception return uses state from <b>PSP</b> . Execution uses <b>PSP</b> after return.
0xFFFF.FFFE - 0xFFFF.FFFF	Reserved

## 2.6 Fault Handling

Faults are a subset of the exceptions (see “Exception Model” on page 82). The following conditions generate a fault:

- A bus error on an instruction fetch or vector table load or a data access.
- An internally detected error such as an undefined instruction or an attempt to change state with a **BX** instruction.
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- An MPU fault because of a privilege violation or an attempt to access an unmanaged region.

### 2.6.1 Fault Types

Table 2-11 on page 91 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates the fault has occurred. See page 143 for more information about the fault status registers.

**Table 2-11. Faults**

Fault	Handler	Fault Status Register	Bit Name
Bus error on a vector read	Hard fault	Hard Fault Status (HFAULTSTAT)	VECT
Fault escalated to a hard fault	Hard fault	Hard Fault Status (HFAULTSTAT)	FORCED
MPU or default memory mismatch on instruction access	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	IERR <sup>a</sup>
MPU or default memory mismatch on data access	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	DERR
MPU or default memory mismatch on exception stacking	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MSTKE
MPU or default memory mismatch on exception unstacking	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MUSTKE
Bus error during exception stacking	Bus fault	Bus Fault Status (BFAULTSTAT)	BSTKE
Bus error during exception unstacking	Bus fault	Bus Fault Status (BFAULTSTAT)	BUSTKE
Bus error during instruction prefetch	Bus fault	Bus Fault Status (BFAULTSTAT)	IBUS
Precise data bus error	Bus fault	Bus Fault Status (BFAULTSTAT)	PRECISE
Imprecise data bus error	Bus fault	Bus Fault Status (BFAULTSTAT)	IMPRE
Attempt to access a coprocessor	Usage fault	Usage Fault Status (UFAULTSTAT)	NOCP
Undefined instruction	Usage fault	Usage Fault Status (UFAULTSTAT)	UNDEF
Attempt to enter an invalid instruction set state <sup>b</sup>	Usage fault	Usage Fault Status (UFAULTSTAT)	INVSTAT
Invalid EXC_RETURN value	Usage fault	Usage Fault Status (UFAULTSTAT)	INVPC
Illegal unaligned load or store	Usage fault	Usage Fault Status (UFAULTSTAT)	UNALIGN
Divide by 0	Usage fault	Usage Fault Status (UFAULTSTAT)	DIV0

a. Occurs on an access to an XN region even if the MPU is disabled.

b. Attempting to use an instruction set other than the Thumb instruction set, or returning to a non load-store-multiple instruction with ICI continuation.

## 2.6.2 Fault Escalation and Hard Faults

All fault exceptions except for hard fault have configurable exception priority (see **SYSPRI1** on page 136). Software can disable execution of the handlers for these faults (see **SYSHNDCTRL** on page 139).

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler as described in “Exception Model” on page 82.

In some situations, a fault with configurable priority is treated as a hard fault. This process is called priority escalation, and the fault is described as *escalated to hard fault*. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This situation happens because the handler for the new fault cannot preempt the currently executing fault handler.

- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. Thus if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

**Note:** Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.

### 2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 2-12 on page 92.

**Table 2-12. Fault Status and Fault Address Registers**

Handler	Status Register Name	Address Register Name	Register Description
Hard fault	Hard Fault Status (HFAULTSTAT)	-	page 149
Memory management fault	Memory Management Fault Status (MFAULTSTAT)	Memory Management Fault Address (MMADDR)	page 143 page 150
Bus fault	Bus Fault Status (BFAULTSTAT)	Bus Fault Address (FAULTADDR)	page 143 page 151
Usage fault	Usage Fault Status (UFAULTSTAT)	-	page 143

### 2.6.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in the lockup state, it does not execute any instructions. The processor remains in lockup state until it is reset or an NMI occurs.

**Note:** If the lockup state occurs from the NMI handler, a subsequent NMI does not cause the processor to leave the lockup state.

## 2.7 Power Management

The Cortex-M3 processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep-sleep mode stops the system clock and switches off the PLL and Flash memory.

The SLEEPDEEP bit of the **System Control (SYSCTRL)** register selects which sleep mode is used (see page 132). For more information about the behavior of the sleep modes, see “System Control” on page 184.

This section describes the mechanisms for entering sleep mode and the conditions for waking up from sleep mode, both of which apply to Sleep mode and Deep-sleep mode.

## 2.7.1 Entering Sleep Modes

This section describes the mechanisms software can use to put the processor into one of the sleep modes.

The system can generate spurious wake-up events, for example a debug operation wakes up the processor. Therefore, software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

### 2.7.1.1 Wait for Interrupt

The wait for interrupt instruction, `WFI`, causes immediate entry to sleep mode unless the wake-up condition is true (see “Wake Up from WFI or Sleep-on-Exit” on page 93). When the processor executes a `WFI` instruction, it stops executing instructions and enters sleep mode. See the *Cortex™-M3 Instruction Set Technical User’s Manual* for more information.

### 2.7.1.2 Wait for Event

The wait for event instruction, `WFE`, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a `WFE` instruction, it checks the event register. If the register is 0, the processor stops executing instructions and enters sleep mode. If the register is 1, the processor clears the register and continues executing instructions without entering sleep mode.

If the event register is 1, the processor must not enter sleep mode on execution of a `WFE` instruction. Typically, this situation occurs if an `SEV` instruction has been executed. Software cannot access this register directly.

See the *Cortex™-M3 Instruction Set Technical User’s Manual* for more information.

### 2.7.1.3 Sleep-on-Exit

If the `SLEEP EXIT` bit of the `SYSCtrl` register is set, when the processor completes the execution of an exception handler, it returns to Thread mode and immediately enters sleep mode. This mechanism can be used in applications that only require the processor to run when an exception occurs.

## 2.7.2 Wake Up from Sleep Mode

The conditions for the processor to wake up depend on the mechanism that cause it to enter sleep mode.

### 2.7.2.1 Wake Up from WFI or Sleep-on-Exit

Normally, the processor wakes up only when it detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up and before executing an interrupt handler. Entry to the interrupt handler can be delayed by setting the `PRIMASK` bit and clearing the `FAULTMASK` bit. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor clears `PRIMASK`. For more information about `PRIMASK` and `FAULTMASK`, see page 70 and page 71.

### 2.7.2.2 Wake Up from WFE

The processor wakes up if it detects an exception with sufficient priority to cause exception entry.

In addition, if the `SEVONPEND` bit in the `SYSCtrl` register is set, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about `SYSCtrl`, see page 132.

## 2.8 Instruction Set Summary

The processor implements a version of the Thumb instruction set. Table 2-13 on page 94 lists the supported instructions.

**Note:** In Table 2-13 on page 94:

- Angle brackets, <>, enclose alternative forms of the operand
- Braces, {}, enclose optional operands
- The Operands column is not exhaustive
- Op2 is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions in the *Cortex™-M3 Instruction Set Technical User's Manual*.

**Table 2-13. Cortex-M3 Instruction Summary**

Mnemonic	Operands	Brief Description	Flags
ADC, ADCS	{Rd, } Rn , Op2	Add with carry	N,Z,C,V
ADD, ADDS	{Rd, } Rn , Op2	Add	N,Z,C,V
ADD, ADDW	{Rd, } Rn , #imm12	Add	N,Z,C,V
ADR	Rd , label	Load PC-relative address	-
AND, ANDS	{Rd , } Rn , Op2	Logical AND	N,Z,C

## 3 Cortex-M3 Peripherals

This chapter provides information on the Stellaris® implementation of the Cortex-M3 processor peripherals, including:

- SysTick (see page 97)
 

Provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism.
- Nested Vectored Interrupt Controller (NVIC) (see page 98)
  - Facilitates low-latency exception and interrupt handling
  - Controls power management
  - Implements system control registers
- System Control Block (SCB) (see page 100)
 

Provides system implementation information and system control, including configuration, control, and reporting of system exceptions.
- Memory Protection Unit (MPU) (see page 100)
 

Supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

Table 3-1 on page 97 shows the address map of the Private Peripheral Bus (PPB). Some peripheral register regions are split into two address regions, as indicated by two addresses listed.

**Table 3-1. Core Peripheral Register Regions**

Address	Core Peripheral	Description (see page ...)
0xE000.E010-0xE000.E01F	System Timer	97
0xE000.E100-0xE000.E4EF 0xE000.EF00-0xE000.EF03	Nested Vectored Interrupt Controller	98
0xE000.ED00-0xE000.ED3F	System Control Block	100
0xE000.ED90-0xE000.EDB8	Memory Protection Unit	100

### 3.1 Functional Description

This chapter provides information on the Stellaris implementation of the Cortex-M3 processor peripherals: SysTick, NVIC, SCB and MPU.

#### 3.1.1 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.

- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNT bit in the **STCTRL** control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the **STRELOAD** register on the next clock edge, then decrements on subsequent clocks. Clearing the **STRELOAD** register disables the counter on the next wrap. When the counter reaches zero, the COUNT status bit is set. The COUNT bit clears on reads.

Writing to the **STCURRENT** register clears the register and the COUNT status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on the processor clock. If this clock signal is stopped for low power mode, the SysTick counter stops. Ensure software uses aligned word accesses to access the SysTick registers.

**Note:** When the processor is halted for debugging, the counter does not decrement.

### 3.1.2 Nested Vectored Interrupt Controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- 41 interrupts.
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling.
- Level and pulse detection of interrupt signals.
- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

### 3.1.2.1 Level-Sensitive and Pulse Interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt (see “Hardware and Software Control of Interrupts” on page 99 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

### 3.1.2.2 Hardware and Software Control of Interrupts

The Cortex-M3 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the **Software Trigger Interrupt (SWTRIG)** register to make a Software-Generated Interrupt pending. See the `INT` bit in the **PEND0** register on page 116 or **SWTRIG** on page 124.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.

If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.

- Software writes to the corresponding interrupt clear-pending register bit
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.

- For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

### 3.1.3 System Control Block (SCB)

The System Control Block (SCB) provides system implementation information and system control, including configuration, control, and reporting of the system exceptions.

### 3.1.4 Memory Protection Unit (MPU)

This section describes the Memory protection unit (MPU). The MPU divides the memory map into a number of regions and defines the location, size, access permissions, and memory attributes of each region. The MPU supports independent attribute settings for each region, overlapping regions, and export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M3 MPU defines eight separate memory regions, 0-7, and a background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M3 MPU memory map is unified, meaning that instruction accesses and data accesses have the same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault, causing a fault exception and possibly causing termination of the process in an OS environment. In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types (see “Memory Regions, Types and Attributes” on page 76 for more information).

Table 3-2 on page 100 shows the possible MPU region attributes. See the section called “MPU Configuration for a Stellaris Microcontroller” on page 104 for guidelines for programming a microcontroller implementation.

**Table 3-2. Memory Attributes Summary**

Memory Type	Description
Strongly Ordered	All accesses to Strongly Ordered memory occur in program order.
Device	Memory-mapped peripherals
Normal	Normal memory

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the **MPU Region Attribute and Size (MPUATTR)** register, all MPU registers must be accessed with aligned word accesses.
- The **MPUATTR** register can be accessed with byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

### 3.1.4.1 Updating an MPU Region

To update the attributes for an MPU region, the **MPU Region Number (MPUNUMBER)**, **MPU Region Base Address (MPUBASE)** and **MPUATTR** registers must be updated. Each register can be programmed separately or with a multiple-word write to program all of these registers. You can use the **MPUBASE<sub>x</sub>** and **MPUATTR<sub>x</sub>** aliases to program up to four regions simultaneously using an STM instruction.

#### *Updating an MPU Region Using Separate Words*

This example simple code configures one region:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER           ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]           ; Region Number
STR R4, [R0, #0x4]           ; Region Base Address
STRH R2, [R0, #0x8]          ; Region Size and Enable
STRH R3, [R0, #0xA]          ; Region Attribute
```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER           ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]           ; Region Number
BIC R2, R2, #1               ; Disable
STRH R2, [R0, #0x8]          ; Region Size and Enable
STR R4, [R0, #0x4]           ; Region Base Address
STRH R3, [R0, #0xA]          ; Region Attribute
ORR R2, #1                  ; Enable
STRH R2, [R0, #0x8]          ; Region Size and Enable
```

Software must use memory barrier instructions:

- Before MPU setup, if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings.
- After MPU setup, if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the Private Peripheral Bus (PPB), which is a Strongly Ordered memory region.

For example, if all of the memory access behavior is intended to take effect immediately after the programming sequence, then a `DSB` instruction and an `ISB` instruction should be used. A `DSB` is required after changing MPU settings, such as at the end of context switch. An `ISB` is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then an `ISB` is not required.

### **Updating an MPU Region Using Multi-Word Writes**

The MPU can be programmed directly using multi-word writes, depending how the information is divided. Consider the following reprogramming:

```
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0] ; Region Number
STR R2, [R0, #0x4] ; Region Base Address
STR R3, [R0, #0x8] ; Region Attribute, Size and Enable
```

An `STM` instruction can be used to optimize this:

```
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STM R0, {R1-R3} ; Region number, address, attribute, size and enable
```

This operation can be done in two words for pre-packed information, meaning that the **MPU Region Base Address (MPUBASE)** register (see page 156) contains the required region number and has the `VALID` bit set. This method can be used when the data is statically packed, for example in a boot loader:

```
; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0] ; Region base address and region number combined
; with VALID (bit 4) set
STR R2, [R0, #0x4] ; Region Attribute, Size and Enable
```

An `STM` instruction can be used to optimize this:

```
; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE ; 0xE000ED9C, MPU Region Base register
STM R0, {R1-R2} ; Region base address, region number and VALID bit,
; and Region Attribute, Size and Enable
```

### **Subregions**

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the `SRD` field of the **MPU Region Attribute and Size (MPUATTR)** register (see page 158) to disable a subregion. The least-significant bit of the `SRD` field controls the first subregion, and the most-significant bit controls the last subregion. Disabling a subregion means another region

overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion, the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, the SRD field must be configured to 0x00, otherwise the MPU behavior is unpredictable.

#### **Example of SRD Use**

Two regions with the same base address overlap. Region one is 128 KB, and region two is 512 KB. To ensure the attributes from region one apply to the first 128 KB region, configure the SRD field for region two to 0x03 to disable the first two subregions, as Figure 3-1 on page 103 shows.

**Figure 3-1. SRD Use Example**

#### **3.1.4.2 MPU Access Permission Attributes**

The access permission bits, TEX, S, C, B, AP, and XN of the **MPUATTR** register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 3-3 on page 103 shows the encodings for the TEX, C, B, and S access permission bits. All encodings are shown for completeness, however the current implementation of the Cortex-M3 does not support the concept of cacheability or shareability. Refer to the section called “MPU Configuration for a Stellaris Microcontroller” on page 104 for information on programming the MPU for Stellaris implementations.

**Table 3-3. TEX, S, C, and B Bit Field Encoding**

TEX	S	C	B	Memory Type	Shareability	Other Attributes
000b	x <sup>a</sup>	0	0	Strongly Ordered	Shareable	-
000	x <sup>a</sup>	0	1	Device	Shareable	-
000	0	1	0	Normal	Not shareable	
000	1	1	0	Normal	Shareable	Outer and inner write-through. No write allocate.
000	0	1	1	Normal	Not shareable	
000	1	1	1	Normal	Shareable	
001	0	0	0	Normal	Not shareable	Outer and inner noncacheable.
001	1	0	0	Normal	Shareable	
001	x <sup>a</sup>	0	1	Reserved encoding	-	-
001	x <sup>a</sup>	1	0	Reserved encoding	-	-
001	0	1	1	Normal	Not shareable	Outer and inner write-back. Write and read allocate.
001	1	1	1	Normal	Shareable	

**Table 3-3. TEX, S, C, and B Bit Field Encoding (continued)**

<b>TEX</b>	<b>S</b>	<b>C</b>	<b>B</b>	<b>Memory Type</b>	<b>Shareability</b>	<b>Other Attributes</b>
010	x <sup>a</sup>	0	0	Device	Not shareable	Nonshared Device.
010	x <sup>a</sup>	0	1	Reserved encoding	-	-
010	x <sup>a</sup>	1	x <sup>a</sup>	Reserved encoding	-	-
1BB	0	A	A	Normal	Not shareable	Cached memory (BB = outer policy, AA = inner policy).
1BB	1	A	A	Normal	Shareable	See Table 3-4 for the encoding of the AA and BB bits.

a. The MPU ignores the value of this bit.

Table 3-4 on page 104 shows the cache policy for memory attribute encodings with a **TEX** value in the range of 0x4-0x7.

**Table 3-4. Cache Policy for Memory Attribute Encoding**

<b>Encoding, AA or BB</b>	<b>Corresponding Cache Policy</b>
00	Non-cacheable
01	Write back, write and read allocate
10	Write through, no write allocate
11	Write back, no write allocate

Table 3-5 on page 104 shows the **AP** encodings in the **MPUATTR** register that define the access permissions for privileged and unprivileged software.

**Table 3-5. AP Bit Field Encoding**

<b>AP Bit Field</b>	<b>Privileged Permissions</b>	<b>Unprivileged Permissions</b>	<b>Description</b>
000	No access	No access	All accesses generate a permission fault.
001	R/W	No access	Access from privileged software only.
010	R/W	RO	Writes by unprivileged software generate a permission fault.
011	R/W	R/W	Full access.
100	Unpredictable	Unpredictable	Reserved.
101	RO	No access	Reads by privileged software only.
110	RO	RO	Read-only, by privileged or unprivileged software.
111	RO	RO	Read-only, by privileged or unprivileged software.

#### **MPU Configuration for a Stellaris Microcontroller**

Stellaris microcontrollers have only a single processor and no caches. As a result, the MPU should be programmed as shown in Table 3-6 on page 104.

**Table 3-6. Memory Region Attributes for Stellaris Microcontrollers**

<b>Memory Region</b>	<b>TEX</b>	<b>S</b>	<b>C</b>	<b>B</b>	<b>Memory Type and Attributes</b>
Flash memory	000b	0	1	0	Normal memory, non-shareable, write-through
Internal SRAM	000b	1	1	0	Normal memory, shareable, write-through

**Table 3-6. Memory Region Attributes for Stellaris Microcontrollers (continued)**

Memory Region	TEX	S	C	B	Memory Type and Attributes
External SRAM	000b	1	1	1	Normal memory, shareable, write-back, write-allocate
Peripherals	000b	1	0	1	Device memory, shareable

In current Stellaris microcontroller implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

### 3.1.4.3 MPU Mismatch

When an access violates the MPU permissions, the processor generates a memory management fault (see “Exceptions and Interrupts” on page 74 for more information). The **MFAULTSTAT** register indicates the cause of the fault. See page 143 for more information.

## 3.2 Register Map

Table 3-7 on page 105 lists the Cortex-M3 Peripheral SysTick, NVIC, SCB, and MPU registers. The offset listed is a hexadecimal increment to the register's address, relative to the Core Peripherals base address of 0xE000.E000.

**Note:** Register spaces that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

**Table 3-7. Peripherals Register Map**

Offset	Name	Type	Reset	Description	See page
<b>System Timer (SysTick) Registers</b>					
0x010	STCTRL	R/W	0x0000.0000	SysTick Control and Status Register	108
0x014	STRELOAD	R/W	0x0000.0000	SysTick Reload Value Register	110
0x018	STCURRENT	R/WC	0x0000.0000	SysTick Current Value Register	111
<b>Nested Vectored Interrupt Controller (NVIC) Registers</b>					
0x100	EN0	R/W	0x0000.0000	Interrupt 0-31 Set Enable	112
0x104	EN1	R/W	0x0000.0000	Interrupt 32-47 Set Enable	113
0x180	DIS0	R/W	0x0000.0000	Interrupt 0-31 Clear Enable	114
0x184	DIS1	R/W	0x0000.0000	Interrupt 32-47 Clear Enable	115

### 3.3 System Timer (SysTick) Register Descriptions

This section lists and describes the System Timer registers, in numerical order by address offset.

## Register 1: SysTick Control and Status Register (STCTRL), offset 0x010

**Note:** This register can only be accessed from privileged mode.

The SysTick **STCTRL** register enables the SysTick features.

### SysTick Control and Status Register (STCTRL)

Base 0xE000.E000  
Offset 0x010  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
16	COUNT	RO	0	<p>Count Flag</p> <table> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>The SysTick timer has not counted to 0 since the last time this bit was read.</td> </tr> <tr> <td>1</td> <td>The SysTick timer has counted to 0 since the last time this bit was read.</td> </tr> </table> <p>This bit is cleared by a read of the register or if the <b>STCURRENT</b> register is written with any value. If read by the debugger using the DAP, this bit is cleared only if the MasterType bit in the <b>AHB-AP Control Register</b> is clear. Otherwise, the COUNT bit is not changed by the debugger read. See the <i>ARM® Debug Interface V5 Architecture Specification</i> for more information on MasterType.</p>	Value	Description	0	The SysTick timer has not counted to 0 since the last time this bit was read.	1	The SysTick timer has counted to 0 since the last time this bit was read.
Value	Description									
0	The SysTick timer has not counted to 0 since the last time this bit was read.									
1	The SysTick timer has counted to 0 since the last time this bit was read.									
15:3	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
2	CLK_SRC	R/W	0	<p>Clock Source</p> <table> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>External reference clock. (Not implemented for Stellaris microcontrollers.)</td> </tr> <tr> <td>1</td> <td>System clock</td> </tr> </table> <p>Because an external reference clock is not implemented, this bit must be set in order for SysTick to operate.</p>	Value	Description	0	External reference clock. (Not implemented for Stellaris microcontrollers.)	1	System clock
Value	Description									
0	External reference clock. (Not implemented for Stellaris microcontrollers.)									
1	System clock									

Bit/Field	Name	Type	Reset	Description
1	INTEN	R/W	0	Interrupt Enable
				Value      Description
			0	Interrupt generation is disabled. Software can use the COUNT bit to determine if the counter has ever reached 0.
			1	An interrupt is generated to the NVIC when SysTick counts to 0.
0	ENABLE	R/W	0	Enable
				Value      Description
			0	The counter is disabled.
			1	Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting.

## Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014

**Note:** This register can only be accessed from privileged mode.

**Note:** This register can only be accessed from privileged mode.

The **STRELOAD** register specifies the start value to load into the **SysTick Current Value (STCURRENT)** register when the counter reaches 0. The start value can be between 0x1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and the COUNT bit are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD field.

### SysTick Reload Value Register (STRELOAD)

Base 0xE000.E000

Offset 0x014

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved										RELOAD					
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RELOAD															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	RELOAD	R/W	0x00.0000	Reload Value Value to load into the <b>SysTick Current Value (STCURRENT)</b> register when the counter reaches 0.

## Register 3: SysTick Current Value Register (STCURRENT), offset 0x018

**Note:** This register can only be accessed from privileged mode.

The **STCURRENT** register contains the current value of the SysTick counter.

### SysTick Current Value Register (STCURRENT)

Base 0xE000.E000  
Offset 0x018  
Type R/WC, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO	R/WC														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CURRENT																
Type	R/WC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	R/WC	0x00.0000	<p>Current Value</p> <p>This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care.</p> <p>This register is write-clear. Writing to it with any value clears the register. Clearing this register also clears the COUNT bit of the <b>STCTRL</b> register.</p>

## 3.4 NVIC Register Descriptions

This section lists and describes the NVIC registers, in numerical order by address offset.

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the **Configuration and Control (CFGCTRL)** register. Any other unprivileged mode access causes a bus fault.

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter the pending state even if it is disabled.

Before programming the **VTABLE** register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts. For more information, see page 129.

## Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100

**Note:** This register can only be accessed from privileged mode.

The **EN0** register enables interrupts and shows which interrupts are enabled. Bit 0 corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31.

See Table 2-9 on page 85 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

### Interrupt 0-31 Set Enable (EN0)

Base 0xE000.E000

Offset 0x100

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Enable
				Value      Description
				0      On a read, indicates the interrupt is disabled. On a write, no effect.
				1      On a read, indicates the interrupt is enabled. On a write, enables the interrupt.

A bit can only be cleared by setting the corresponding `INT[n]` bit in the **DISn** register.

## Register 5: Interrupt 32-47 Set Enable (EN1), offset 0x104

**Note:** This register can only be accessed from privileged mode.

The **EN1** register enables interrupts and shows which interrupts are enabled. Bit 0 corresponds to Interrupt 32; bit 15 corresponds to Interrupt 47. See Table 2-9 on page 85 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

### Interrupt 32-47 Set Enable (EN1)

Base 0xE000.E000

Offset 0x104

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
INT																
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### Bit/Field Name Type Reset Description

31:16 reserved RO 0x000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

15:0 INT R/W 0x0.0000 Interrupt Enable

Value	Description
0	On a read, indicates the interrupt is disabled. On a write, no effect.
1	On a read, indicates the interrupt is enabled. On a write, enables the interrupt.

A bit can only be cleared by setting the corresponding `INT[n]` bit in the **DIS1** register.

## Register 6: Interrupt 0-31 Clear Enable (DIS0), offset 0x180

**Note:** This register can only be accessed from privileged mode.

The **DIS0** register disables interrupts. Bit 0 corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31.

See Table 2-9 on page 85 for interrupt assignments.

### Interrupt 0-31 Clear Enable (DIS0)

Base 0xE000.E000

Offset 0x180

Type R/W, reset 0x0000.0000

Bit/Field      Name      Type      Reset      Description

31:0      INT      R/W      0x0000.0000      Interrupt Disable

Value	Description
0	On a read, indicates the interrupt is disabled. On a write, no effect.
1	On a read, indicates the interrupt is enabled. On a write, clears the corresponding <code>INT[n]</code> bit in the <b>EN0</b> register, disabling interrupt [n].

## Register 7: Interrupt 32-47 Clear Enable (DIS1), offset 0x184

**Note:** This register can only be accessed from privileged mode.

The **DIS1** register disables interrupts. Bit 0 corresponds to Interrupt 32; bit 15 corresponds to Interrupt 47. See Table 2-9 on page 85 for interrupt assignments.

### Interrupt 32-47 Clear Enable (DIS1)

Base 0xE000.E000  
Offset 0x184  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
INT																
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	INT	R/W	0x0.0000	Interrupt Disable
	Value	Description		
	0	On a read, indicates the interrupt is disabled. On a write, no effect.		
	1	On a read, indicates the interrupt is enabled. On a write, clears the corresponding INT[n] bit in the <b>EN1</b> register, disabling interrupt [n].		

## Register 8: Interrupt 0-31 Set Pending (PEND0), offset 0x200

**Note:** This register can only be accessed from privileged mode.

The **PEND0** register forces interrupts into the pending state and shows which interrupts are pending. Bit 0 corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31.

See Table 2-9 on page 85 for interrupt assignments.

### Interrupt 0-31 Set Pending (PEND0)

Base 0xE000.E000

Offset 0x200

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Set Pending
				Value      Description
			0	On a read, indicates that the interrupt is not pending. On a write, no effect.
			1	On a read, indicates that the interrupt is pending. On a write, the corresponding interrupt is set to pending even if it is disabled.
				If the corresponding interrupt is already pending, setting a bit has no effect.
				A bit can only be cleared by setting the corresponding INT[n] bit in the <b>UNPEND0</b> register.

## Register 9: Interrupt 32-47 Set Pending (PEND1), offset 0x204

**Note:** This register can only be accessed from privileged mode.

The **PEND1** register forces interrupts into the pending state and shows which interrupts are pending. Bit 0 corresponds to Interrupt 32; bit 15 corresponds to Interrupt 47. See Table 2-9 on page 85 for interrupt assignments.

### Interrupt 32-47 Set Pending (PEND1)

Base 0xE000.E000  
Offset 0x204  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
INT																
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	INT	R/W	0x0.0000	Interrupt Set Pending
				Value Description
			0	On a read, indicates that the interrupt is not pending. On a write, no effect.
			1	On a read, indicates that the interrupt is pending. On a write, the corresponding interrupt is set to pending even if it is disabled.
				If the corresponding interrupt is already pending, setting a bit has no effect.
				A bit can only be cleared by setting the corresponding <code>INT[n]</code> bit in the <b>UNPEND1</b> register.

## Register 10: Interrupt 0-31 Clear Pending (UNPEND0), offset 0x280

**Note:** This register can only be accessed from privileged mode.

The **UNPEND0** register shows which interrupts are pending and removes the pending state from interrupts. Bit 0 corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31.

See Table 2-9 on page 85 for interrupt assignments.

### Interrupt 0-31 Clear Pending (UNPEND0)

Base 0xE000.E000

Offset 0x280

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	R/W	0x0000.0000	Interrupt Clear Pending
Value Description				
0	On a read, indicates that the interrupt is not pending. On a write, no effect.			
1	On a read, indicates that the interrupt is pending. On a write, clears the corresponding <code>INT[n]</code> bit in the <b>PEND0</b> register, so that interrupt [n] is no longer pending. Setting a bit does not affect the active state of the corresponding interrupt.			

## Register 11: Interrupt 32-47 Clear Pending (UNPEND1), offset 0x284

**Note:** This register can only be accessed from privileged mode.

The **UNPEND1** register shows which interrupts are pending and removes the pending state from interrupts. Bit 0 corresponds to Interrupt 32; bit 15 corresponds to Interrupt 47. See Table 2-9 on page 85 for interrupt assignments.

### Interrupt 32-47 Clear Pending (UNPEND1)

Base 0xE000.E000  
Offset 0x284  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INT																
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	INT	R/W	0x0.0000	Interrupt Clear Pending
		Value	Description	
		0	On a read, indicates that the interrupt is not pending. On a write, no effect.	
		1	On a read, indicates that the interrupt is pending. On a write, clears the corresponding INT[n] bit in the PEND1 register, so that interrupt [n] is no longer pending. Setting a bit does not affect the active state of the corresponding interrupt.	

## Register 12: Interrupt 0-31 Active Bit (ACTIVE0), offset 0x300

**Note:** This register can only be accessed from privileged mode.

The **ACTIVE0** register indicates which interrupts are active. Bit 0 corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31.

See Table 2-9 on page 85 for interrupt assignments.

**Caution – Do not manually set or clear the bits in this register.**

### Interrupt 0-31 Active Bit (ACTIVE0)

Base 0xE000.E000

Offset 0x300

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	INT	RO	0x0000.0000	Interrupt Active

Value	Description
0	The corresponding interrupt is not active.
1	The corresponding interrupt is active, or active and pending.

## Register 13: Interrupt 32-47 Active Bit (ACTIVE1), offset 0x304

**Note:** This register can only be accessed from privileged mode.

The **ACTIVE1** register indicates which interrupts are active. Bit 0 corresponds to Interrupt 32; bit 15 corresponds to Interrupt 47. See Table 2-9 on page 85 for interrupt assignments.

**Caution – Do not manually set or clear the bits in this register.**

### Interrupt 32-47 Active Bit (ACTIVE1)

Base 0xE000.E000  
Offset 0x304  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	INT	RO	0x0.0000	Interrupt Active
		Value	Description	
		0	The corresponding interrupt is not active.	
		1	The corresponding interrupt is active, or active and pending.	

- Register 14: Interrupt 0-3 Priority (PRI0), offset 0x400**
- Register 15: Interrupt 4-7 Priority (PRI1), offset 0x404**
- Register 16: Interrupt 8-11 Priority (PRI2), offset 0x408**
- Register 17: Interrupt 12-15 Priority (PRI3), offset 0x40C**
- Register 18: Interrupt 16-19 Priority (PRI4), offset 0x410**
- Register 19: Interrupt 20-23 Priority (PRI5), offset 0x414**
- Register 20: Interrupt 24-27 Priority (PRI6), offset 0x418**
- Register 21: Interrupt 28-31 Priority (PRI7), offset 0x41C**
- Register 22: Interrupt 32-35 Priority (PRI8), offset 0x420**
- Register 23: Interrupt 36-39 Priority (PRI9), offset 0x424**
- Register 24: Interrupt 40-43 Priority (PRI10), offset 0x428**
- Register 25: Interrupt 44-47 Priority (PRI11), offset 0x42C**

**Note:** This register can only be accessed from privileged mode.

The **PRI<sub>n</sub>** registers provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

PRIn Register Bit Field	Interrupt
Bits 31:29	Interrupt [4n+3]
Bits 23:21	Interrupt [4n+2]
Bits 15:13	Interrupt [4n+1]
Bits 7:5	Interrupt [4n]

See Table 2-9 on page 85 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The PRIGROUP field in the **Application Interrupt and Reset Control (APINT)** register (see page 130) indicates the position of the binary point that splits the priority and subpriority fields .

These registers can only be accessed from privileged mode.

#### Interrupt 0-3 Priority (PRI0)

Bit/Field	Name	Type	Reset	Description
31:29	INTD	R/W	0x0	Interrupt Priority for Interrupt [4n+3] This field holds a priority value, 0-7, for the interrupt with the number [4n+3], where n is the number of the <b>Interrupt Priority</b> register (n=0 for <b>PRI0</b> , and so on). The lower the value, the greater the priority of the corresponding interrupt.
28:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:21	INTC	R/W	0x0	Interrupt Priority for Interrupt [4n+2] This field holds a priority value, 0-7, for the interrupt with the number [4n+2], where n is the number of the <b>Interrupt Priority</b> register (n=0 for <b>PRI0</b> , and so on). The lower the value, the greater the priority of the corresponding interrupt.
20:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:13	INTB	R/W	0x0	Interrupt Priority for Interrupt [4n+1] This field holds a priority value, 0-7, for the interrupt with the number [4n+1], where n is the number of the <b>Interrupt Priority</b> register (n=0 for <b>PRI0</b> , and so on). The lower the value, the greater the priority of the corresponding interrupt.
12:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	INTA	R/W	0x0	Interrupt Priority for Interrupt [4n] This field holds a priority value, 0-7, for the interrupt with the number [4n], where n is the number of the <b>Interrupt Priority</b> register (n=0 for <b>PRI0</b> , and so on). The lower the value, the greater the priority of the corresponding interrupt.
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 26: Software Trigger Interrupt (SWTRIG), offset 0xF00

**Note:** Only privileged software can enable unprivileged access to the **SWTRIG** register.

Writing an interrupt number to the **SWTRIG** register generates a Software Generated Interrupt (SGI). See Table 2-9 on page 85 for interrupt assignments.

When the **MAINPEND** bit in the **Configuration and Control (CFGCTRL)** register (see page 134) is set, unprivileged software can access the **SWTRIG** register.

### Software Trigger Interrupt (SWTRIG)

Base 0xE000.E000  
Offset 0xF00  
Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	INTID	WO	0x00	Interrupt ID This field holds the interrupt ID of the required SGI. For example, a value of 0x3 generates an interrupt on IRQ3.

## 3.5 System Control Block (SCB) Register Descriptions

This section lists and describes the System Control Block (SCB) registers, in numerical order by address offset. The SCB registers can only be accessed from privileged mode.

All registers must be accessed with aligned word accesses except for the **FAULTSTAT** and **SYSPRI1-SYSPRI3** registers, which can be accessed with byte or aligned halfword or word accesses. The processor does not support unaligned accesses to system control block registers.

## Register 27: CPU ID Base (CPUID), offset 0xD00

**Note:** This register can only be accessed from privileged mode.

The **CPUID** register contains the ARM® Cortex™-M3 processor part number, version, and implementation information.

### CPU ID Base (CPUID)

Base 0xE000.E000

Offset 0xD00

Type RO, reset 0x411F.C231

Bit/Field	Name	Type	Reset	Description
31:24	IMP	RO	0x41	Implementer Code Value Description 0x41 ARM
23:20	VAR	RO	0x1	Variant Number Value Description 0x1 The rn value in the rnpn product revision identifier, for example, the 1 in r1p1.
19:16	CON	RO	0xF	Constant Value Description 0xF Always reads as 0xF.
15:4	PARTNO	RO	0xC23	Part Number Value Description 0xC23 Cortex-M3 processor.
3:0	REV	RO	0x1	Revision Number Value Description 0x1 The pn value in the rnpn product revision identifier, for example, the 1 in r1p1.

## Register 28: Interrupt Control and State (INTCTRL), offset 0xD04

**Note:** This register can only be accessed from privileged mode.

The **INTCTRL** register provides a set-pending bit for the NMI exception, and set-pending and clear-pending bits for the PendSV and SysTick exceptions. In addition, bits in this register indicate the exception number of the exception being processed, whether there are preempted active exceptions, the exception number of the highest priority pending exception, and whether any interrupts are pending.

When writing to **INTCTRL**, the effect is unpredictable when writing a 1 to both the PENDSV and UNPENDSV bits, or writing a 1 to both the PENDSTSET and PENDSTCLR bits.

### Interrupt Control and State (INTCTRL)

Base 0xE000.E000  
Offset 0xD04

#### Bit/Field      Name      Type      Reset      Description

31            NMISET      R/W      0      NMI Set Pending

##### Value Description

- 0      On a read, indicates an NMI exception is not pending.  
On a write, no effect.
- 1      On a read, indicates an NMI exception is pending.  
On a write, changes the NMI exception state to pending.

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers the setting of this bit, and clears this bit on entering the interrupt handler. A read of this bit by the NMI exception handler returns 1 only if the **NMI** signal is reasserted while the processor is executing that handler.

30:29           reserved      RO      0x0      Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

28            PENDSV      R/W      0      PendSV Set Pending

##### Value Description

- 0      On a read, indicates a PendSV exception is not pending.  
On a write, no effect.
- 1      On a read, indicates a PendSV exception is pending.  
On a write, changes the PendSV exception state to pending.

Setting this bit is the only way to set the PendSV exception state to pending. This bit is cleared by writing a 1 to the UNPENDSV bit.

Bit/Field	Name	Type	Reset	Description						
27	UNPENDSV	WO	0	<p>PendSV Clear Pending</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>On a write, no effect.</td></tr> <tr> <td>1</td><td>On a write, removes the pending state from the PendSV exception.</td></tr> </tbody> </table> <p>This bit is write only; on a register read, its value is unknown.</p>	Value	Description	0	On a write, no effect.	1	On a write, removes the pending state from the PendSV exception.

## Register 29: Vector Table Offset (VTABLE), offset 0xD08

**Note:** This register can only be accessed from privileged mode.

The **VTABLE** register indicates the offset of the vector table base address from memory address 0x0000.0000.

### Vector Table Offset (VTABLE)

Base 0xE000.E000

Offset 0xD08

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO	RO	R/W													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
OFFSET																
Type	R/W	RO														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
reserved																

Bit/Field	Name	Type	Reset	Description
31:30	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
29	BASE	R/W	0	Vector Table Base
	Value	Description		
	0	The vector table is in the code memory region.		
	1	The vector table is in the SRAM memory region.		
28:8	OFFSET	R/W	0x000.00	Vector Table Offset When configuring the OFFSET field, the offset must be aligned to the number of exception entries in the vector table. Because there are 47 interrupts, the minimum alignment is 64 words.
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## **Register 30: Application Interrupt and Reset Control (APINT), offset 0xD0C**

**Note:** This register can only be accessed from privileged mode.

The **APINT** register provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system. To write to this register, 0x05FA must be written to the VECTKEY field, otherwise the write is ignored.

The PRIGROUP field indicates the position of the binary point that splits the INTx fields in the **Interrupt Priority (PRIx)** registers into separate group priority and subpriority fields. Table 3-8 on page 130 shows how the PRIGROUP value controls this split. The bit numbers in the Group Priority Field and Subpriority Field columns in the table refer to the bits in the INTA field. For the INTB field, the corresponding bits are 15:13; for INTC, 23:21; and for INTD, 31:29.

**Note:** Determining preemption of an exception uses only the group priority field.

**Table 3-8. Interrupt Priority Levels**

PRIGROUP Bit Field	Binary Point <sup>a</sup>	Group Priority Field	Subpriority Field	Group Priorities	Subpriorities
0x0 - 0x4	bxxx.	[7:5]	None	8	1
0x5	bxx.y	[7:6]	[5]	4	2
0x6	bx.yy	[7]	[6:5]	2	4
0x7	b.yyy	None	[7:5]	1	8

a. INTx field showing the binary point. An x denotes a group priority field bit, and a y denotes a subpriority field bit.

## Application Interrupt and Reset Control (APINT)

Base 0xE000.E000  
Offset 0xD0C  
Type R/W reset 0xFA05 0000

Bit/Field	Name	Type	Reset	Description
31:16	VECTKEY	R/W	0xFA05	<p>Register Key</p> <p>This field is used to guard against accidental writes to this register. 0x05FA must be written to this field in order to change the bits in this register. On a read, 0xFA05 is returned.</p>
15	ENDIANESS	RO	0	<p>Data Endianess</p> <p>The Stellaris implementation uses only little-endian mode so this is cleared to 0.</p>
14:11	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description						
10:8	PRIGROUP	R/W	0x0	Interrupt Priority Grouping This field determines the split of group priority from subpriority (see Table 3-8 on page 130 for more information).						
7:3	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Value	Description									
0	No effect.									
1	Resets the core and all on-chip peripherals except the Debug interface.									
1	VECTCLRACT	WO	0	Clear Active NMI / Fault This bit is reserved for Debug use and reads as 0. This bit must be written as a 0, otherwise behavior is unpredictable.						
0	VECTRESET	WO	0	System Reset This bit is reserved for Debug use and reads as 0. This bit must be written as a 0, otherwise behavior is unpredictable.						

## Register 31: System Control (SYSCTRL), offset 0xD10

**Note:** This register can only be accessed from privileged mode.

The **SYSCTRL** register controls features of entry to and exit from low-power state.

### System Control (SYSCTRL)

Base 0xE000.E000  
Offset 0xD10  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SEVONPEND	R/W	0	<p>Wake Up on Pending</p> <p>Value Description</p> <p>0 Only enabled interrupts or events can wake up the processor; disabled interrupts are excluded.</p> <p>1 Enabled events and all interrupts, including disabled interrupts, can wake up the processor.</p> <p>When an event or interrupt enters the pending state, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE.</p> <p>The processor also wakes up on execution of a SEV instruction or an external event.</p>
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	SLEEPDEEP	R/W	0	<p>Deep Sleep Enable</p> <p>Value Description</p> <p>0 Use Sleep mode as the low power mode.</p> <p>1 Use Deep-sleep mode as the low power mode.</p>

Bit/Field	Name	Type	Reset	Description						
1	SLEEP EXIT	R/W	0	<p>Sleep on ISR Exit</p> <table> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>When returning from Handler mode to Thread mode, do not sleep when returning to Thread mode.</td> </tr> <tr> <td>1</td> <td>When returning from Handler mode to Thread mode, enter sleep or deep sleep on return from an ISR.</td> </tr> </tbody> </table> <p>Setting this bit enables an interrupt-driven application to avoid returning to an empty main application.</p>	Value	Description	0	When returning from Handler mode to Thread mode, do not sleep when returning to Thread mode.	1	When returning from Handler mode to Thread mode, enter sleep or deep sleep on return from an ISR.
Value	Description									
0	When returning from Handler mode to Thread mode, do not sleep when returning to Thread mode.									
1	When returning from Handler mode to Thread mode, enter sleep or deep sleep on return from an ISR.									
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						

## Register 32: Configuration and Control (CFGCTRL), offset 0xD14

**Note:** This register can only be accessed from privileged mode.

The **CFGCTRL** register controls entry to Thread mode and enables: the handlers for NMI, hard fault and faults escalated by the **FAULTMASK** register to ignore bus faults; trapping of divide by zero and unaligned accesses; and access to the **SWTRIG** register by unprivileged software (see page 124).

### Configuration and Control (CFGCTRL)

Base 0xE000.E000  
Offset 0xD14  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	STKALIGN	R/W	0	<p>Stack Alignment on Exception Entry</p> <p>Value Description</p> <p>0 The stack is 4-byte aligned.</p> <p>1 The stack is 8-byte aligned.</p> <p>On exception entry, the processor uses bit 9 of the stacked <b>PSR</b> to indicate the stack alignment. On return from the exception, it uses this stacked bit to restore the correct stack alignment.</p>
8	BFHFNMIGN	R/W	0	<p>Ignore Bus Fault in NMI and Fault</p> <p>This bit enables handlers with priority -1 or -2 to ignore data bus faults caused by load and store instructions. The setting of this bit applies to the hard fault, NMI, and <b>FAULTMASK</b> escalated handlers.</p> <p>Value Description</p> <p>0 Data bus faults caused by load and store instructions cause a lock-up.</p> <p>1 Handlers running at priority -1 and -2 ignore data bus faults caused by load and store instructions.</p> <p>Set this bit only when the handler and its data are in absolutely safe memory. The normal use of this bit is to probe system devices and bridges to detect control path problems and fix them.</p>
7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description

4:0	reserved	RO	0x0.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 36: System Handler Control and State (SYSHNDCTRL), offset 0xD24

**Note:** This register can only be accessed from privileged mode.

The **SYSHNDCTRL** register enables the system handlers, and indicates the pending status of the usage fault, bus fault, memory management fault, and SVC exceptions as well as the active status of the system handlers.

If a system handler is disabled and the corresponding fault occurs, the processor treats the fault as a hard fault.

This register can be modified to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

**Caution – Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.**

**If the value of a bit in this register must be modified after enabling the system handlers, a read-modify-write procedure must be used to ensure that only the required bit is modified.**

0 Memory management fault is not active.				
1 Memory management fault is active.				
This bit can be modified to change the active status of the memory management fault exception, however, see the Caution above before setting this bit.				

## Register 37: Configurable Fault Status (FAULTSTAT), offset 0xD28

**Note:** This register can only be accessed from privileged mode.

The **FAULTSTAT** register indicates the cause of a memory management fault, bus fault, or usage fault. Each of these functions is assigned to a subregister as follows:

- **Usage Fault Status (UFAULTSTAT)**, bits 31:16
- **Bus Fault Status (BFAULTSTAT)**, bits 15:8
- **Memory Management Fault Status (MFAULTSTAT)**, bits 7:0

**FAULTSTAT** is byte accessible. **FAULTSTAT** or its subregisters can be accessed as follows:

- The complete **FAULTSTAT** register, with a word access to offset 0xD28
- The **MFAULTSTAT**, with a byte access to offset 0xD28
- The **MFAULTSTAT** and **BFAULTSTAT**, with a halfword access to offset 0xD28
- The **BFAULTSTAT**, with a byte access to offset 0xD29
- The **UFAULTSTAT**, with a halfword access to offset 0xD2A

Bits are cleared by writing a 1 to them.

In a fault handler, the true faulting address can be determined by:

1. Read and save the **Memory Management Fault Address (MMADDR)** or **Bus Fault Address (FAULTADDR)** value.
2. Read the **MMARV** bit in **MFAULTSTAT**, or the **BFARV** bit in **BFAULTSTAT** to determine if the **MMADDR** or **FAULTADDR** contents are valid.

Software must follow this sequence because another higher priority exception might change the **MMADDR** or **FAULTADDR** value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the **MMADDR** or **FAULTADDR** value.

Bit/Field	Name	Type	Reset	Description
31	DBG	R/W1C	0	Debug Event This bit is reserved for Debug use. This bit must be written as a 0, otherwise behavior is unpredictable.
30	FORCED	R/W1C	0	Forced Hard Fault  Value Description 0 No forced hard fault has occurred. 1 A forced hard fault has been generated by escalation of a fault with configurable priority that cannot be handled, either because of priority or because it is disabled.  When this bit is set, the hard fault handler must read the other fault status registers to find the cause of the fault. This bit is cleared by writing a 1 to it.
29:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	VECT	R/W1C	0	Vector Table Read Fault  Value Description 0 No bus fault has occurred on a vector table read. 1 A bus fault occurred on a vector table read.  This error is always handled by the hard fault handler. When this bit is set, the <b>PC</b> value stacked for the exception return points to the instruction that was preempted by the exception. This bit is cleared by writing a 1 to it.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 39: Memory Management Fault Address (MMADDR), offset 0xD34

**Note:** This register can only be accessed from privileged mode.

The **MMADDR** register contains the address of the location that generated a memory management fault. When an unaligned access faults, the address in the **MMADDR** register is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size. Bits in the **Memory Management Fault Status (MFAULTSTAT)** register indicate the cause of the fault and whether the value in the **MMADDR** register is valid (see page 143).

### Memory Management Fault Address (MMADDR)

Base 0xE000.E000

Offset 0xD34

Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Fault Address When the MMARV bit of MFAULTSTAT is set, this field holds the address of the location that generated the memory management fault.

## Register 40: Bus Fault Address (FAULTADDR), offset 0xD38

**Note:** This register can only be accessed from privileged mode.

The **FAULTADDR** register contains the address of the location that generated a bus fault. When an unaligned access faults, the address in the **FAULTADDR** register is the one requested by the instruction, even if it is not the address of the fault. Bits in the **Bus Fault Status (BFAULTSTAT)** register indicate the cause of the fault and whether the value in the **FAULTADDR** register is valid (see page 143).

### Bus Fault Address (FAULTADDR)

Base 0xE000.E000

Offset 0xD38

Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Fault Address When the FAULTADDRV bit of <b>BFAULTSTAT</b> is set, this field holds the address of the location that generated the bus fault.

## 3.6 Memory Protection Unit (MPU) Register Descriptions

This section lists and describes the Memory Protection Unit (MPU) registers, in numerical order by address offset.

The MPU registers can only be accessed from privileged mode.

## Register 41: MPU Type (MPUTYPE), offset 0xD90

**Note:** This register can only be accessed from privileged mode.

The **MPUTYPE** register indicates whether the MPU is present, and if so, how many regions it supports.

### MPU Type (MPUTYPE)

Base 0xE000.E000

Offset 0xD90

Type RO, reset 0x0000.0800

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:16	IREGION	RO	0x00	Number of I Regions This field indicates the number of supported MPU instruction regions. This field always contains 0x00. The MPU memory map is unified and is described by the DREGION field.
15:8	DREGION	RO	0x08	Number of D Regions  Value Description 0x08 Indicates there are eight supported MPU data regions.
7:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	SEPARATE	RO	0	Separate or Unified MPU  Value Description 0 Indicates the MPU is unified.

## Register 42: MPU Control (MPUCTRL), offset 0xD94

**Note:** This register can only be accessed from privileged mode.

The **MPUCTRL** register enables the MPU, enables the default memory map background region, and enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and **Fault Mask Register (FAULTMASK)** escalated handlers.

When the **ENABLE** and **PRIVDEFEN** bits are both set:

- For privileged accesses, the default memory map is as described in “Memory Model” on page 74. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

Execute Never (XN) and Strongly Ordered rules always apply to the System Control Space regardless of the value of the **ENABLE** bit.

When the **ENABLE** bit is set, at least one region of the memory map must be enabled for the system to function unless the **PRIVDEFEN** bit is set. If the **PRIVDEFEN** bit is set and no regions are enabled, then only privileged software can operate.

When the **ENABLE** bit is clear, the system uses the default memory map, which has the same memory attributes as if the MPU is not implemented (see Table 2-5 on page 77 for more information). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether **PRIVDEFEN** is set.

Unless **HFNMIENA** is set, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception or when **FAULTMASK** is enabled. Setting the **HFNMIENA** bit enables the MPU when operating with these two priorities.

### MPU Control (MPUCTRL)

Value	Description									
0	The MPU is disabled.									
1	The MPU is enabled.									

## Register 43: MPU Region Number (MPUNUMBER), offset 0xD98

**Note:** This register can only be accessed from privileged mode.

The **MPUNUMBER** register selects which memory region is referenced by the **MPU Region Base Address (MPUBASE)** and **MPU Region Attribute and Size (MPUATTR)** registers. Normally, the required region number should be written to this register before accessing the **MPUBASE** or the **MPUATTR** register. However, the region number can be changed by writing to the **MPUBASE** register with the **VALID** bit set (see page 156). This write updates the value of the **REGION** field.

### MPU Region Number (MPUNUMBER)

Base 0xE000.E000  
Offset 0xD98  
Type R/W, reset 0x0000.0000

**Register 44: MPU Region Base Address (MPUBASE), offset 0xD9C****Register 45: MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4****Register 46: MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC****Register 47: MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4**

**Note:** This register can only be accessed from privileged mode.

The **MPUBASE** register defines the base address of the MPU region selected by the **MPU Region Number (MPUNUMBER)** register and can update the value of the **MPUNUMBER** register. To change the current region number and update the **MPUNUMBER** register, write the **MPUBASE** register with the **VALID** bit set.

The **ADDR** field is bits 31:N of the **MPUBASE** register. Bits (N-1):5 are reserved. The region size, as specified by the **SIZE** field in the **MPU Region Attribute and Size (MPUATTR)** register, defines the value of N where:

$$N = \log_2(\text{Region size in bytes})$$

If the region size is configured to 4 GB in the **MPUATTR** register, there is no valid **ADDR** field. In this case, the region occupies the complete memory map, and the base address is 0x0000.0000.

The base address is aligned to the size of the region. For example, a 64-KB region must be aligned on a multiple of 64 KB, for example, at 0x0001.0000 or 0x0002.0000.

#### MPU Region Base Address (MPUBASE)

REGION															

Bit/Field	Name	Type	Reset	Description
31:5	ADDR	R/W	0x0000.0000	<p>Base Address Mask</p> <p>Bits 31:N in this field contain the region base address. The value of N depends on the region size, as shown above. The remaining bits (N-1):5 are reserved.</p> <p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>

Bit/Field	Name	Type	Reset	Description
4	VALID	WO	0	Region Number Valid  Value Description 0 The <b>MPUNUMBER</b> register is not changed and the processor updates the base address for the region specified in the <b>MPUNUMBER</b> register and ignores the value of the REGION field. 1 The <b>MPUNUMBER</b> register is updated with the value of the REGION field and the base address is updated for the region specified in the REGION field.  This bit is always read as 0.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	REGION	R/W	0x0	Region Number On a write, contains the value to be written to the <b>MPUNUMBER</b> register. On a read, returns the current region number in the <b>MPUNUMBER</b> register.

**Register 48: MPU Region Attribute and Size (MPUATTR), offset 0xDA0****Register 49: MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8****Register 50: MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0****Register 51: MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8**

**Note:** This register can only be accessed from privileged mode.

The **MPUATTR** register defines the region size and memory attributes of the MPU region specified by the **MPU Region Number (MPUNUMBER)** register and enables that region and any subregions.

The **MPUATTR** register is accessible using word or halfword accesses with the most-significant halfword holding the region attributes and the least-significant halfword holds the region size and the region and subregion enable bits.

The MPU access permission attribute bits, XN, AP, TEX, S, C, and B, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

The SIZE field defines the size of the MPU memory region specified by the **MPUNUMBER** register as follows:

$$(\text{Region size in bytes}) = 2^{(\text{SIZE}+1)}$$

The smallest permitted region size is 32 bytes, corresponding to a SIZE value of 4. Table 3-9 on page 158 gives example SIZE values with the corresponding region size and value of N in the **MPU Region Base Address (MPUBASE)** register.

**Table 3-9. Example SIZE Field Values**

SIZE Encoding	Region Size	Value of N <sup>a</sup>	Note
00100b (0x4)	32 B	5	Minimum permitted size
01001b (0x9)	1 KB	10	-
10011b (0x13)	1 MB	20	-
11101b (0x1D)	1 GB	30	-
11111b (0x1F)	4 GB	No valid ADDR field in <b>MPUBASE</b> ; the region occupies the complete memory map.	Maximum possible size

a. Refers to the N parameter in the **MPUBASE** register (see page 156).

## 4 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Stellaris® JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core. This is implemented by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Stellaris JTAG instructions select the Stellaris TDO outputs. The multiplexer is controlled by the Stellaris JTAG controller, which has comprehensive programming for the ARM, Stellaris, and unimplemented JTAG instructions.

The Stellaris JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)

See the *ARM® Debug Interface V5 Architecture Specification* for more information on the ARM JTAG controller.

## 4.1 Block Diagram

Figure 4-1. JTAG Module Block Diagram

## 4.2 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 4-1 on page 162. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST and INTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 4-2 on page 169 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 815 for JTAG timing diagrams.

## 4.2.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated reset state are given in Table 4-1 on page 163. Detailed information on each pin follows.

**Table 4-1. JTAG Port Pins Reset State**

Pin Name	Data Direction	Internal Pull-Up	Internal Pull-Down	Drive Strength	Drive Value
TCK	Input	Enabled	Disabled	N/A	N/A
TMS	Input	Enabled	Disabled	N/A	N/A
TDI	Input	Enabled	Disabled	N/A	N/A
TDO	Output	Enabled	Disabled	2-mA driver	High-Z

### 4.2.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks. In addition, it ensures that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset. This assures that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source.

### 4.2.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state is entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 4-2 on page 165.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost.

### 4.2.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, presents this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost.

#### 4.2.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset. This assures that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states.

#### 4.2.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 4-2 on page 165. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the device has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

**Figure 4-2. Test Access Port State Machine**

### 4.2.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out of TDO during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 168.

#### **4.2.4 Operational Considerations**

There are certain operational considerations when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

#### 4.2.4.1 GPIO Functionality

When the controller is reset with either a POR or  $\overline{\text{RST}}$ , the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality (setting **GPIODEN** to 1), enabling the pull-up resistors (setting **GPIOPUR** to 1), and enabling the alternate hardware function (setting **GPIOAFSEL** to 1) for the  $\text{PC}[3:0]$  JTAG/SWD pins.

It is possible for software to configure these pins as GPIOs after reset by writing 0s to  $\text{PC}[3:0]$  in the **GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

---

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. This may lock the debugger out of the part. This can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.**

---

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin ( $\text{PB7}$ ) and the four JTAG/SWD pins ( $\text{PC}[3:0]$ ). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 378), **GPIO Pull-Up Select (GPIOPUR)** register (see page 384), and **GPIO Digital Enable (GPIODEN)** register (see page 388) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 390) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 391) have been set to 1.

#### *Recovering a "Locked" Device*

**Note:** Performing the sequence below causes the nonvolatile registers discussed in “Nonvolatile Register Programming” on page 272 to be restored to their factory default values. The mass erase of the flash memory caused by the below sequence occurs prior to the nonvolatile registers being restored.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug sequence that can be used to recover the device. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the device in reset mass erases the flash memory. The sequence to recover the device is:

1. Assert and hold the  $\overline{\text{RST}}$  signal.
2. Perform the JTAG-to-SWD switch sequence.
3. Perform the SWD-to-JTAG switch sequence.
4. Perform the JTAG-to-SWD switch sequence.
5. Perform the SWD-to-JTAG switch sequence.
6. Perform the JTAG-to-SWD switch sequence.
7. Perform the SWD-to-JTAG switch sequence.
8. Perform the JTAG-to-SWD switch sequence.
9. Perform the SWD-to-JTAG switch sequence.

10. Perform the JTAG-to-SWD switch sequence.
11. Perform the SWD-to-JTAG switch sequence.
12. Release the  $\overline{RST}$  signal.
13. Wait 400 ms.
14. Power-cycle the device.

The JTAG-to-SWD and SWD-to-JTAG switch sequences are described in “ARM Serial Wire Debug (SWD)” on page 167. When performing switch sequences for the purpose of recovering the debug capabilities of the device, only steps 1 and 2 of the switch sequence in the section called “JTAG-to-SWD Switching” on page 167 must be performed.

#### 4.2.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock (TCK or SWCLK), the previous operation has enough time to complete and the ACK bits do not have to be checked.

#### 4.2.4.3 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M3 core without having to perform, or have any knowledge of, JTAG cycles. This is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequences of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Debug Interface V5 Architecture Specification*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This is the only instance where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

#### **JTAG-to-SWD Switching**

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the device. The 16-bit switch sequence for switching to SWD mode is defined as b1110011110011110, transmitted LSB first. This can also be represented as 16'hE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit JTAG-to-SWD switch sequence, 16'hE79E.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that if SWJ-DP was already in SWD mode, before sending the switch sequence, the SWD goes into the line reset state.

#### **SWD-to-JTAG Switching**

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch sequence to the device. The 16-bit switch sequence for switching to JTAG mode is defined as b1110011100111100, transmitted LSB first. This can also be represented as 16'hE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit SWD-to-JTAG switch sequence, 16'hE73C.
3. Send at least 5 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that if SWJ-DP was already in JTAG mode, before sending the switch sequence, the JTAG goes into the Test Logic Reset state.

### **4.3 Initialization and Configuration**

After a Power-On-Reset or an external reset ( $\overline{\text{RST}}$ ), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. This is done by enabling the four JTAG pins ( $\text{PC[3:0]}$ ) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins ( $\text{PC[3:0]}$ ) should be reverted to their default settings.

### **4.4 Register Descriptions**

There are no APB-accessible registers in the JTAG TAP Controller or Shift Register chains. The registers within the JTAG controller are all accessed serially through the TAP Controller. The registers can be broken down into two main categories: Instruction Registers and Data Registers.

#### **4.4.1 Instruction Register (IR)**

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TDO pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the Instruction Register. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the Instruction Register bits is shown in Table 4-2 on page 169. A detailed explanation of each instruction, along with its associated Data Register, follows.

**Table 4-2. JTAG Instruction Register Commands**

IR[3:0]	Instruction	Description
0000	EXTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.
0001	INTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.
0010	SAMPLE / PRELOAD	Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in.
1000	ABORT	Shifts data into the ARM Debug Port Abort Register.
1010	DPACC	Shifts data into and out of the ARM DP Access Register.
1011	APACC	Shifts data into and out of the ARM AC Access Register.
1110	IDCODE	Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.
1111	BYPASS	Connects TDI to TDO through a single Shift Register chain.
All Others	Reserved	Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.

#### 4.4.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. The EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. This allows tests to be developed that drive known values out of the controller, which can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 4.4.1.2 INTEST Instruction

The INTEST instruction is not associated with its own Data Register chain. The INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. This allows tests to be developed that drive known values into the controller, which can be used for testing. While the INTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 4.4.1.3 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out of TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI.

Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. Please see “Boundary Scan Data Register” on page 171 for more information.

#### 4.4.1.4 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. Please see the “ABORT Data Register” on page 172 for more information.

#### 4.4.1.5 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. Please see “DPACC Data Register” on page 172 for more information.

#### 4.4.1.6 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. Please see “APACC Data Register” on page 172 for more information.

#### 4.4.1.7 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure their input and output data streams. IDCODE is the default instruction that is loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. Please see “IDCODE Data Register” on page 171 for more information.

#### 4.4.1.8 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. Please see “BYPASS Data Register” on page 171 for more information.

### 4.4.2 Data Registers

The JTAG module contains six Data Registers. These include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT serial Data Register chains. Each of these Data Registers is discussed in the following sections.

#### 4.4.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-3 on page 171. The standard requires that every JTAG-compliant device implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This allows auto configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly, and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x3BA0.0477. This allows the debuggers to automatically configure themselves to work correctly with the Cortex-M3 during debug.

**Figure 4-3. IDCODE Register Format**

#### 4.4.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-4 on page 171. The standard requires that every JTAG-compliant device implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This allows auto configuration test tools to determine which instruction is the default instruction.

**Figure 4-4. BYPASS Register Format**

#### 4.4.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 4-5 on page 172. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as can be seen in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. These instructions either force data out of the controller, with the EXTEST instruction, or into the controller, with the INTEST instruction.

**Figure 4-5. Boundary Scan Register Format**

#### 4.4.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### 4.4.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

#### 4.4.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

# 5 System Control

System control determines the overall operation of the device. It provides information about the device, controls the clocking to the core and individual peripherals, and handles reset detection and reporting.

## 5.1 Functional Description

The System Control module provides the following capabilities:

- Device identification (see “Device Identification” on page 173)
- Local control, such as reset (see “Reset Control” on page 173), power (see “Power Control” on page 178) and clock control (see “Clock Control” on page 178)
- System control (Run, Sleep, and Deep-Sleep modes); see “System Control” on page 184

### 5.1.1 Device Identification

Several read-only registers provide software with information on the microcontroller, such as version, part number, SRAM size, flash size, and other features. See the **DID0**, **DID1**, and **DC0-DC7** registers.

### 5.1.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

#### 5.1.2.1 Reset Sources

The controller has six sources of reset:

1. External reset input pin ( $\overline{RST}$ ) assertion; see “External  $\overline{RST}$  Pin” on page 174.
2. Power-on reset (POR); see “Power-On Reset (POR)” on page 174.
3. Internal brown-out (BOR) detector; see “Brown-Out Reset (BOR)” on page 176.
4. Software-initiated reset (with the software reset registers); see “Software Reset” on page 176.
5. A watchdog timer reset condition violation; see “Watchdog Timer Reset” on page 177.
6. MOSC failure; see “Main Oscillator Verification Failure” on page 177.

Table 5-1 provides a summary of results of the various reset operations.

**Table 5-1. Reset Sources**

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset? <sup>a</sup>
Power-On Reset	Yes	Yes	Yes
$\overline{RST}$	Yes	Pin Config Only	Yes
Brown-Out Reset	Yes	No	Yes
Software System Request Reset <sup>b</sup>	Yes	No	Yes
Software Peripheral Reset	No	No	Yes <sup>c</sup>

**Table 5-1. Reset Sources (continued)**

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset? <sup>a</sup>
Watchdog Reset	Yes	No	Yes
MOSC Failure Reset	Yes	No	Yes

a. Refer to "Register Reset" on page 254 for information on how reset affects the Hibernation module.

b. By using the SYSRESREQ bit in the ARM Cortex-M3 Application Interrupt and Reset Control (APINT) register

c. Programmable on a module-by-module basis using the Software Reset Control Registers.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, and then all the other bits in the **RESC** register are cleared except for the POR indicator.

### 5.1.2.2 Power-On Reset (POR)

**Note:** The power-on reset also resets the JTAG controller. An external reset does not.

The internal Power-On Reset (POR) circuit monitors the power supply voltage ( $V_{DD}$ ) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value ( $V_{TH}$ ). The microcontroller must be operating within the specified operating parameters when the on-chip power-on reset pulse is complete. The 3.3-V power supply to the microcontroller must reach 3.0 V within 10 msec of  $V_{DD}$  crossing 2.0 V to guarantee proper operation. For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the  $\overline{RST}$  input may be used as discussed in "External  $\overline{RST}$  Pin" on page 174.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller. The Power-On Reset timing is shown in Figure 23-5 on page 817.

### 5.1.2.3 External $\overline{RST}$ Pin

**Note:** It is recommended that the trace for the  $\overline{RST}$  signal must be kept as short as possible. Be sure to place any components connected to the  $\overline{RST}$  signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the  $\overline{RST}$  input must be connected to the power supply ( $V_{DD}$ ) through an optional pull-up resistor (0 to 100K  $\Omega$ ) as shown in Figure 5-1 on page 175.

**Figure 5-1. Basic  $\overline{\text{RST}}$  Configuration**

$$R_{PU} = 0 \text{ to } 100 \text{ k}\Omega$$

The external reset pin ( $\overline{\text{RST}}$ ) resets the microcontroller including the core and all the on-chip peripherals except the JTAG TAP controller (see “JTAG Interface” on page 161). The external reset sequence is as follows:

1. The external reset pin ( $\overline{\text{RST}}$ ) is asserted for the duration specified by  $T_{MIN}$  and then de-asserted (see “Reset” on page 817).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

To improve noise immunity and/or to delay reset at power up, the  $\overline{\text{RST}}$  input may be connected to an RC network as shown in Figure 5-2 on page 175.

**Figure 5-2. External Circuitry to Extend Power-On Reset**

$$R_{PU} = 1 \text{ k}\Omega \text{ to } 100 \text{ k}\Omega$$

$$C_1 = 1 \text{ nF to } 10 \mu\text{F}$$

If the application requires the use of an external reset switch, Figure 5-3 on page 176 shows the proper circuitry to use.

**Figure 5-3. Reset Circuit Controlled by Switch**

Typical  $R_{PU} = 10\text{ k}\Omega$

Typical  $R_S = 470\text{ }\Omega$

$C_1 = 10\text{ nF}$

The  $R_{PU}$  and  $C_1$  components define the power-on delay.

The external reset timing is shown in Figure 23-4 on page 817.

#### 5.1.2.4 Brown-Out Reset (BOR)

A drop in the input voltage resulting in the assertion of the internal brown-out detector can be used to reset the controller. This is initially disabled and may be enabled by software.

The system provides a brown-out detection circuit that triggers if the power supply ( $V_{DD}$ ) drops below a brown-out threshold voltage ( $V_{BTH}$ ). If a brown-out condition is detected, the system may generate a controller interrupt or a system reset.

Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The **BORIOR** bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset.

The brown-out reset is equivalent to an assertion of the external  $\overline{RST}$  input and the reset is held active until the proper  $V_{DD}$  level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 23-6 on page 818.

#### 5.1.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire system .

Peripherals can be individually reset by software via three registers that control reset signals to each peripheral (see the **SRCRn** registers). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset. The encoding of the reset registers is consistent with the encoding of the clock gating control for peripherals and on-chip functions (see “System Control” on page 184). Note that all reset signals for all clocks of the specified unit are asserted as a result of a software-initiated reset.

The entire system can be reset by software by setting the **SYSRESETREQ** bit in the Cortex-M3 Application Interrupt and Reset Control register resets the entire system including the core. The software-initiated system reset sequence is as follows:

1. A software system reset is initiated by writing the SYSRESETREQ bit in the ARM Cortex-M3 Application Interrupt and Reset Control register.
2. An internal reset is asserted.
3. The internal reset is deasserted and the controller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 23-7 on page 818.

### 5.1.2.6 Watchdog Timer Reset

The watchdog timer module's function is to prevent system hangs. The watchdog timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out.

After the first time-out event, the 32-bit counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the system. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the controller loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The watchdog reset timing is shown in Figure 23-8 on page 818.

## 5.1.3 Non-Maskable Interrupt

The controller has two sources of non-maskable interrupt (NMI):

- The assertion of the NMI signal.
- A main oscillator verification error.

If both sources of NMI are enabled, software must check that the main oscillator verification is the cause of the interrupt in order to distinguish between the two sources.

### 5.1.3.1 NMI Pin

The alternate function to GPIO port pin B7 is an NMI signal. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 359. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality. The active sense of the NMI signal is High; asserting the enabled NMI signal above  $V_{IH}$  initiates the NMI interrupt sequence.

### 5.1.3.2 Main Oscillator Verification Failure

The main oscillator verification circuit may generate a reset event, at which time a Power-on Reset is generated and control is transferred to the NMI handler. The NMI handler is used to address the

main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled using the `CVAL` bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status bit (`MOSCFAIL`) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Clock Control” on page 178.

#### 5.1.4 Power Control

The Stellaris® microcontroller provides an integrated LDO regulator that may be used to provide power to the majority of the controller's internal logic. For power reduction, the LDO regulator provides software a mechanism to adjust the regulated value, in small increments (VSTEP), over the range of 2.25 V to 2.75 V (inclusive)—or  $2.5\text{ V} \pm 10\%$ . The adjustment is made by changing the value of the `VADJ` field in the **LDO Power Control (LDOPCTL)** register.

**Note:** On the printed circuit board, use the `LDO` output as the source of `VDD25` input. Do not use an external regulator to supply the voltage to `VDD25`. In addition, the LDO requires decoupling capacitors. See “On-Chip Low Drop-Out (LDO) Regulator Characteristics” on page 811.

`VDDA` must be supplied with 3.3 V, or the microcontroller does not function properly. `VDDA` is the supply for all of the analog circuitry on the device, including the clock circuitry.

#### 5.1.5 Clock Control

System control determines the control of clocks in this part.

##### 5.1.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the device:

- **Internal Oscillator (IOSC).** The internal oscillator is an on-chip clock source. It does not require the use of any external components. The frequency of the internal oscillator is  $12\text{ MHz} \pm 30\%$ . Applications that do not depend on accurate clock sources may use this clock source to reduce system cost. The internal oscillator is the clock source the device uses during and following POR. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference.
- **Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the `OSC0` input pin, or an external crystal is connected across the `OSC0` input and `OSC1` output pins. If the PLL is being used, the crystal value must be one of the supported frequencies between 3.579545 MHz through 16.384 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 1 MHz and 16.384 MHz. The single-ended clock source range is from DC through the specified speed of the device. The supported crystals are listed in the `XTAL` bit field in the **RCC** register (see page 196). Note that the MOSC must have a clock source for the USB PLL.
- **Internal 30-kHz Oscillator.** The internal 30-kHz oscillator is similar to the internal oscillator, except that it provides an operational frequency of  $30\text{ kHz} \pm 50\%$ . It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the main oscillator to be powered down.
- **External Real-Time Oscillator.** The external real-time oscillator provides a low-frequency, accurate clock reference. It is intended to provide the system with a real-time clock source. The real-time oscillator is part of the Hibernation Module (see “Hibernation Module” on page 247) and may also provide an accurate source of Deep-Sleep or Hibernate mode power savings.

The internal system clock (SysClk), is derived from any of the above sources plus two others: the output of the main internal PLL, and the internal oscillator divided by four ( $3\text{ MHz} \pm 30\%$ ). The frequency of the PLL clock reference must be in the range of 3.579545 MHz to 16.384 MHz (inclusive). Table 5-2 on page 179 shows how the various clock sources can be used in a system.

**Table 5-2. Clock Source Options**

Clock Source	Drive PLL?	Used as SysClk?		
Internal Oscillator (12 MHz)	No	BYPASS = 1	Yes	BYPASS = 1, OSCSRC = 0x1
Internal Oscillator divide by 4 (3 MHz)	No	BYPASS = 1	Yes	BYPASS = 1, OSCSRC = 0x2
Main Oscillator	Yes	BYPASS = 0, OSCSRC = 0x0	Yes	BYPASS = 1, OSCSRC = 0x0
Internal 30-kHz Oscillator	No	BYPASS = 1	Yes	BYPASS = 1, OSCSRC = 0x3
External Real-Time Oscillator	No	BYPASS = 1	Yes	BYPASS = 1, OSCSRC2 = 0x7

### 5.1.5.2 Clock Configuration

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options. These registers control the following clock functionality:

- Source of clocks in sleep and deep-sleep modes
- System clock derived from PLL or other clock source
- Enabling/disabling of oscillators and PLL
- Clock divisors
- Crystal input selection

Figure 5-4 on page 180 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled. The ADC clock signal is automatically divided down to 16 MHz for proper ADC operation. The PWM clock signal is a synchronous divide of the system clock to provide the PWM circuit with more range (set with PWMDIV in **RCC**).

**Note:** When the ADC module is in operation, the system clock must be at least 16 MHz.

**Figure 5-4. Main Clock Tree**

a. Control provided by RCC register bit/field.

b. Control provided by RCC register bit/field or RCC2 register bit/field, if overridden with RCC2 register bit USERCC2.

c. Control provided by RCC2 register bit/field.

d. Also may be controlled by DSLPCLKCFG when in deep sleep mode.

**Note:** The figure above shows all features available on all Stellaris® DustDevil-class devices. Not all peripherals may be available on this device.

In the **RCC** register, the **SYSDIV** field specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the **BYPASS** bit in this register is configured). When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. Table 5-3 shows how the **SYSDIV** encoding affects the system clock frequency, depending on whether the PLL is used (**BYPASS=0**) or another clock source is used (**BYPASS=1**). The divisor is equivalent to the **SYSDIV** encoding plus 1. For a list of possible clock sources, see Table 5-2 on page 179.

**Table 5-3. Possible System Clock Frequencies Using the SYSDIV Field**

SYSDIV	Divisor	Frequency (BYPASS=0)	Frequency (BYPASS=1)	StellarisWare Parameter <sup>a</sup>
0x0	/1	reserved	Clock source frequency/2	SYSCTL_SYSDIV_1 <sup>b</sup>
0x1	/2	reserved	Clock source frequency/2	SYSCTL_SYSDIV_2
0x2	/3	reserved	Clock source frequency/3	SYSCTL_SYSDIV_3
0x3	/4	50 MHz	Clock source frequency/4	SYSCTL_SYSDIV_4
0x4	/5	40 MHz	Clock source frequency/5	SYSCTL_SYSDIV_5
0x5	/6	33.33 MHz	Clock source frequency/6	SYSCTL_SYSDIV_6
0x6	/7	28.57 MHz	Clock source frequency/7	SYSCTL_SYSDIV_7
0x7	/8	25 MHz	Clock source frequency/8	SYSCTL_SYSDIV_8
0x8	/9	22.22 MHz	Clock source frequency/9	SYSCTL_SYSDIV_9
0x9	/10	20 MHz	Clock source frequency/10	SYSCTL_SYSDIV_10
0xA	/11	18.18 MHz	Clock source frequency/11	SYSCTL_SYSDIV_11
0xB	/12	16.67 MHz	Clock source frequency/12	SYSCTL_SYSDIV_12
0xC	/13	15.38 MHz	Clock source frequency/13	SYSCTL_SYSDIV_13
0xD	/14	14.29 MHz	Clock source frequency/14	SYSCTL_SYSDIV_14
0xE	/15	13.33 MHz	Clock source frequency/15	SYSCTL_SYSDIV_15
0xF	/16	12.5 MHz (default)	Clock source frequency/16	SYSCTL_SYSDIV_16

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCTL\_SYSDIV\_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

The SYSDIV2 field in the **RCC2** register is 2 bits wider than the SYSDIV field in the **RCC** register so that additional larger divisors up to /64 are possible, allowing a lower system clock frequency for improved Deep Sleep power consumption. When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. The divisor is equivalent to the SYSDIV2 encoding plus 1. Table 5-4 shows how the SYSDIV2 encoding affects the system clock frequency, depending on whether the PLL is used (BYPASS2=0) or another clock source is used (BYPASS2=1). For a list of possible clock sources, see Table 5-2 on page 179.

**Table 5-4. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field**

SYSDIV2	Divisor	Frequency (BYPASS2=0)	Frequency (BYPASS2=1)	StellarisWare Parameter <sup>a</sup>
0x00	/1	reserved	Clock source frequency/2	SYSCTL_SYSDIV_1 <sup>b</sup>
0x01	/2	reserved	Clock source frequency/2	SYSCTL_SYSDIV_2
0x02	/3	reserved	Clock source frequency/3	SYSCTL_SYSDIV_3
0x03	/4	50 MHz	Clock source frequency/4	SYSCTL_SYSDIV_4
0x04	/5	40 MHz	Clock source frequency/5	SYSCTL_SYSDIV_5
0x05	/6	33.33 MHz	Clock source frequency/6	SYSCTL_SYSDIV_6
0x06	/7	28.57 MHz	Clock source frequency/7	SYSCTL_SYSDIV_7
0x07	/8	25 MHz	Clock source frequency/8	SYSCTL_SYSDIV_8
0x08	/9	22.22 MHz	Clock source frequency/9	SYSCTL_SYSDIV_9
0x09	/10	20 MHz	Clock source frequency/10	SYSCTL_SYSDIV_10
...	...	...	...	...

**Table 5-4. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field  
(continued)**

SYSDIV2	Divisor	Frequency (BYPASS2=0)	Frequency (BYPASS2=1)	StellarisWare Parameter <sup>a</sup>
0x3F	/64	3.125 MHz	Clock source frequency/64	SYSCTL_SYSDIV_64

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCTL\_SYSDIV\_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

### 5.1.5.3 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals. If the main oscillator is used by the PLL as a reference clock, the supported range of crystals is 3.579545 to 16.384 MHz, otherwise, the range of supported crystals is 1 to 16.384 MHz.

The XTAL bit in the **RCC** register (see page 196) describes the available crystal choices and default programming values.

Software configures the **RCC** register XTAL field with the crystal number. If the PLL is used in the design, the XTAL field value is internally translated to the PLL settings.

### 5.1.5.4 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency, and enables the main PLL to drive the output. The PLL operates at 400 MHz, but is divided by two prior to the application of the output divisor.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **XTAL to PLL Translation (PLLCFG)** register (see page 200). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 23-10 on page 814 shows the actual PLL frequency and error for a given crystal choice.

The Crystal Value field (XTAL) in the **Run-Mode Clock Configuration (RCC)** register (see page 196) describes the available crystal choices and default programming of the **PLLCFG** register. Any time the XTAL field changes, the new settings are translated and the internal PLL settings are updated.

To configure the external 32-kHz real-time oscillator as the PLL input reference, program the OSCRC2 field in the **Run-Mode Clock Configuration 2 (RCC2)** register to be 0x7.

### 5.1.5.5 USB PLL Frequency Configuration

The USB PLL is disabled by default during power-on reset and is enabled later by software. The USB PLL must be enabled and running for proper USB function. The main oscillator is the only clock reference for the USB PLL. The USB PLL is enabled by clearing the USBPWRDN bit of the **RCC2** register. The XTAL bit field (Crystal Value) of the **RCC** register describes the available crystal choices. The main oscillator must be connected to one of the following crystal values in order to correctly generate the USB clock: 4, 5, 6, 8, 10, 12, or 16 MHz. Only these crystals provide the necessary USB PLL VCO frequency to conform with the USB timing specifications.

### 5.1.5.6 PLL Modes

Both PLLs have two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.

- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 196 and page 203).

#### 5.1.5.7 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is  $T_{READY}$  (see Table 23-9 on page 814). During the relock time, the affected PLL is not usable as a clock reference.

Either PLL is changed by one of the following:

- Change to the `XTAL` value in the **RCC** register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter is defined to measure the  $T_{READY}$  requirement. The counter is clocked by the main oscillator. The range of the main oscillator has been taken into account and the down counter is set to 0x1200 (that is, ~600  $\mu$ s at an 8.192 MHz external oscillator clock). When the `XTAL` value is greater than 0x0f, the down counter is set to 0x2400 to maintain the required lock time on higher frequency crystal inputs. Hardware is provided to keep the PLL from being used as a system clock until the  $T_{READY}$  condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the controller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable ( $T_{READY}$  time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the `PLLRLIS` bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

The USB PLL is not protected during the lock time ( $T_{READY}$ ) and software should ensure that the USB PLL has locked before using the interface. Software can use many methods to ensure the  $T_{READY}$  period has passed, including periodically polling the `USBPLLRLIS` bit in the **Raw Interrupt Status (RIS)** register, and enabling the USB PLL Lock interrupt.

#### 5.1.5.8 Main Oscillator Verification Circuit

A circuit is added to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the `CVAL` bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, the following sequence is performed by the hardware:

1. The `MOSCFAIL` bit in the **Reset Cause (RESC)** register is set.
2. If the internal oscillator (IOSC) is disabled, it is enabled.
3. The system clock is switched from the main oscillator to the IOSC.
4. An internal power-on reset is initiated that lasts for 32 IOSC periods.
5. Reset is de-asserted and the processor is directed to the NMI handler during the reset sequence.

### 5.1.6 System Control

For power-savings purposes, the **RCGCr**, **SCGCr**, and **DCGCr** registers control the clock gating logic for each peripheral or block in the system while the controller is in Run, Sleep, and Deep-Sleep mode, respectively.

There are four levels of operation for the device defined as:

- **Run Mode.** In Run mode, the controller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the **RCGCr** registers. The system clock can be any of the available clock sources including the PLL.
- **Sleep Mode.** In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M3 core executing a **WFI** (Wait for Interrupt) instruction. Any properly configured interrupt event in the system will bring the processor back into Run mode. See “Power Management” on page 92 for more details.

Peripherals are clocked that are enabled in the **SCGCr** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCr** register when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

- **Deep-Sleep Mode.** In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the device to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first writing the Deep Sleep Enable bit in the ARM Cortex-M3 NVIC system control register and then executing a **WFI** instruction. Any properly configured interrupt event in the system will bring the processor back into Run mode. See “Power Management” on page 92 for more details.

The Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **DCGCr** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCr** register when auto-clock gating is disabled. The system clock source is the main oscillator by default or the internal oscillator specified in the **DSLPCLKCFG** register if one is enabled. When the **DSLPCLKCFG** register is used, the internal oscillator is powered up, if necessary, and the main oscillator is powered down. If the PLL is running at the time of the **WFI** instruction, hardware will power the PLL down and override the **SYS DIV** field of the active **RCC/RCC2** register, to be determined by the **DSDIVORIDE** setting in the **DSLPCLKCFG** register, up to /16 or /64 respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration.

- **Hibernate Mode.** In this mode, the power supplies are turned off to the main part of the device and only the Hibernation module's circuitry is active. An external wake event or RTC event is required to bring the device back to Run mode. The Cortex-M3 processor and peripherals outside of the Hibernation module see a normal “power on” sequence and the processor starts running code. It can determine that it has been restarted from Hibernate mode by inspecting the Hibernation module registers.

**Caution – If the Cortex-M3 Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.**

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a WFI (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power-cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

## 5.2 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the **USERCC2** bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the **BYPASS** bit and clearing the **USESYS** bit in the **RCC** register. This configures the system to run off a “raw” clock source and allows for the new PLL configuration to be validated before switching the system clock to the PLL.
2. Select the crystal value (**XTAL**) and oscillator source (**OSCSRC**), and clear the **PWRDN** bit in **RCC/RCC2**. Setting the **XTAL** field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the **PWRDN** bit powers and enables the PLL and its output.
3. Select the desired system divider (**SYSDIV**) in **RCC/RCC2** and set the **USESYS** bit in **RCC**. The **SYSDIV** field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the **PLLRLIS** bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the **BYPASS** bit in **RCC/RCC2**.

## 5.3 Register Map

Table 5-5 on page 185 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

**Note:** Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

**Note:** Additional Flash and ROM registers defined in the System Control register space are described in the “Internal Memory” on page 269.

**Table 5-5. System Control Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	DID0	RO	-	Device Identification 0	188
0x004	DID1	RO	-	Device Identification 1	207
0x008	DC0	RO	0x00FF.003F	Device Capabilities 0	209

**Table 5-5. System Control Register Map (continued)**

Offset	Name	Type	Reset	Description	See page
0x010	DC1	RO	0x0011.33FF	Device Capabilities 1	210
0x014	DC2	RO	0x030F.5133	Device Capabilities 2	212
0x018	DC3	RO	0xBFFF.86FF	Device Capabilities 3	214

## **5.4 Register Descriptions**

All addresses given are relative to the System Control base address of 0x400F.E000.

## Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the device.

### Device Identification 0 (DID0)

Base 0x400F.E000  
Offset 0x000  
Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30:28	VER	RO	0x1	DID0 Version This field defines the <b>DID0</b> register format version. The version number is numeric. The value of the <b>VER</b> field is encoded as follows:  Value Description 0x1 Second version of the <b>DID0</b> register format.
27:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:16	CLASS	RO	0x3	Device Class The <b>CLASS</b> field value identifies the internal design from which all mask sets are generated for all devices in a particular product line. The <b>CLASS</b> field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the <b>MAJOR</b> or <b>MINOR</b> fields require differentiation from prior devices. The value of the <b>CLASS</b> field is encoded as follows (all other encodings are reserved):  Value Description 0x3 Stellaris® DustDevil-class devices

Bit/Field	Name	Type	Reset	Description								
15:8	MAJOR	RO	-	<p>Major Revision</p> <p>This field specifies the major revision number of the device. The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Revision A (initial device)</td></tr> <tr> <td>0x1</td><td>Revision B (first base layer revision)</td></tr> <tr> <td>0x2</td><td>Revision C (second base layer revision)</td></tr> </tbody> </table> <p>and so on.</p>	Value	Description	0x0	Revision A (initial device)	0x1	Revision B (first base layer revision)	0x2	Revision C (second base layer revision)
Value	Description											
0x0	Revision A (initial device)											
0x1	Revision B (first base layer revision)											
0x2	Revision C (second base layer revision)											
7:0	MINOR	RO	-	<p>Minor Revision</p> <p>This field specifies the minor revision number of the device. The minor revision reflects changes to the metal layers of the design. The MINOR field value is reset when the MAJOR field is changed. This field is numeric and is encoded as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Initial device, or a major revision update.</td></tr> <tr> <td>0x1</td><td>First metal layer change.</td></tr> <tr> <td>0x2</td><td>Second metal layer change.</td></tr> </tbody> </table> <p>and so on.</p>	Value	Description	0x0	Initial device, or a major revision update.	0x1	First metal layer change.	0x2	Second metal layer change.
Value	Description											
0x0	Initial device, or a major revision update.											
0x1	First metal layer change.											
0x2	Second metal layer change.											

## Register 2: Brown-Out Reset Control (PBORCTL), offset 0x030

This register is responsible for controlling reset conditions after initial power-on reset.

### Brown-Out Reset Control (PBORCTL)

Base 0x400F.E000  
Offset 0x030  
Type R/W, reset 0x0000.7FFD

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIOR	R/W	0	BOR Interrupt or Reset This bit controls how a BOR event is signaled to the controller. If set, a reset is signaled. Otherwise, an interrupt is signaled.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 3: LDO Power Control (LDOPCTL), offset 0x034

The VADJ field in this register adjusts the on-chip output voltage ( $V_{OUT}$ ).

### LDO Power Control (LDOPCTL)

Base 0x400F.E000  
Offset 0x034  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	VADJ	R/W	0x0	LDO Output Voltage This field sets the on-chip output voltage. The programming values for the VADJ field are provided below.

Value	$V_{OUT}$ (V)
0x00	2.50
0x01	2.45
0x02	2.40
0x03	2.35
0x04	2.30
0x05	2.25
0x06-0x3F	Reserved
0x1B	2.75
0x1C	2.70
0x1D	2.65
0x1E	2.60
0x1F	2.55

## Register 4: Raw Interrupt Status (RIS), offset 0x050

Central location for system control raw interrupts. These are set and cleared by hardware.

### Raw Interrupt Status (RIS)

Base 0x400F.E000  
Offset 0x050  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPRIS	RO	0	MOSC Power Up Raw Interrupt Status This bit is set when the PLL $T_{MOSCPUP}$ Timer asserts.
7	USBPLLRLIS	RO	0	USB PLL Lock Raw Interrupt Status This bit is set when the USB PLL $T_{USBREADY}$ Timer asserts.
6	PLLLRIS	RO	0	PLL Lock Raw Interrupt Status This bit is set when the PLL $T_{READY}$ Timer asserts.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORRIS	RO	0	Brown-Out Reset Raw Interrupt Status This bit is the raw interrupt status for any brown-out conditions. If set, a brown-out condition is currently active. This is an unregistered signal from the brown-out detection circuit. An interrupt is reported if the BORIM bit in the IMC register is set and the BORIOR bit in the PBORCTL register is cleared.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 5: Interrupt Mask Control (IMC), offset 0x054

Central location for system control interrupt masks.

### Interrupt Mask Control (IMC)

Base 0x400F.E000  
Offset 0x054  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
reserved																
Type	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	RO	RO	RO	R/W	R/W	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
reserved																
Type	RO	RO	RO	RO	RO	RO	MOSCPUPIM	USBPLLIM	PLLLIM	reserved				BORIM	reserved	
Reset	0	0	0	0	0	0	0	0	0	reserved				0	0	

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPIM	R/W	0	MOSC Power Up Interrupt Mask This bit specifies whether a MOSC power up interrupt is promoted to a controller interrupt. If set, an interrupt is generated if <b>MOSCPUPRIS</b> in <b>RIS</b> is set; otherwise, an interrupt is not generated.
7	USBPLLIM	R/W	0	USB PLL Lock Interrupt Mask This bit specifies whether a USB PLL Lock interrupt is promoted to a controller interrupt. If set, an interrupt is generated if <b>USBPLLRLIS</b> in <b>RIS</b> is set; otherwise, an interrupt is not generated.
6	PLLLIM	R/W	0	PLL Lock Interrupt Mask This bit specifies whether a PLL Lock interrupt is promoted to a controller interrupt. If set, an interrupt is generated if <b>PLLLRLIS</b> in <b>RIS</b> is set; otherwise, an interrupt is not generated.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIM	R/W	0	Brown-Out Reset Interrupt Mask This bit specifies whether a brown-out condition is promoted to a controller interrupt. If set, an interrupt is generated if <b>BORRIS</b> is set; otherwise, an interrupt is not generated.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt. All of the bits are R/W1C and this action also clears the corresponding raw interrupt bit in the **RIS** register (see page 192).

### Masked Interrupt Status and Clear (MISC)

Base 0x400F.E000  
Offset 0x058  
Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPMIS	R/W1C	0	MOSC Power Up Masked Interrupt Status This bit is set when the $T_{MOSCPUP}$ timer asserts. The interrupt is cleared by writing a 1 to this bit.
7	USBPLLIMIS	R/W1C	0	USB PLL Lock Masked Interrupt Status This bit is set when the USB PLL $T_{USBREADY}$ timer asserts. The interrupt is cleared by writing a 1 to this bit.
6	PLLLMIS	R/W1C	0	PLL Lock Masked Interrupt Status This bit is set when the PLL $T_{READY}$ timer asserts. The interrupt is cleared by writing a 1 to this bit.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORMIS	R/W1C	0	BOR Masked Interrupt Status The BORMIS is simply the BORRIS ANDed with the mask value, BORIM.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 7: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences, except when a power-on reset is the cause, in which case, all bits other than POR in the **RESC** register are cleared.

### Reset Cause (RESC)

Base 0x400F.E000

Offset 0x05C

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16			
	reserved														MOSCFAIL

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
	reserved														SW	WDT	BOR	POR	EXT
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W		
Reset	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-		

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	MOSCFAIL	R/W	-	MOSC Failure Reset When set, indicates the MOSC circuit was enable for clock validation and failed. This generated a reset event.
15:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SW	R/W	-	Software Reset When set, indicates a software reset is the cause of the reset event.
3	WDT	R/W	-	Watchdog Timer Reset When set, indicates a watchdog reset is the cause of the reset event.
2	BOR	R/W	-	Brown-Out Reset When set, indicates a brown-out reset is the cause of the reset event.
1	POR	R/W	-	Power-On Reset When set, indicates a power-on reset is the cause of the reset event.
0	EXT	R/W	-	External Reset When set, indicates an external reset ( $\overline{RST}$ assertion) is the cause of the reset event.

## Register 8: Run-Mode Clock Configuration (RCC), offset 0x060

This register is defined to provide source control and frequency speed.

### Run-Mode Clock Configuration (RCC)

Base 0x400F.E000  
Offset 0x060  
Type R/W, reset 0x078E.3AD1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved				ACG	SYSDIV				USESYSDIV	reserved	USEPWMDIV	PWMDIV			
Type	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	RO	R/W	R/W	R/W	R/W	R/W	RO
Reset	0	0	0	0	0	1	1	1	1	0	0	0	1	1	1	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved				PWRDN	reserved	BYPASS	XTAL				OSCSRC	reserved			
Type	RO	RO	R/W	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	RO	RO	R/W	R/W
Reset	0	0	1	1	1	0	1	0	1	1	0	1	0	0	0	1

Bit/Field	Name	Type	Reset	Description
31:28	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
27	ACG	R/W	0	<p>Auto Clock Gating</p> <p>This bit specifies whether the system uses the <b>Sleep-Mode Clock Gating Control (SCGCn)</b> registers and <b>Deep-Sleep-Mode Clock Gating Control (DCGCn)</b> registers if the controller enters a Sleep or Deep-Sleep mode (respectively). If set, the <b>SCGCn</b> or <b>DCGCn</b> registers are used to control the clocks distributed to the peripherals when the controller is in a sleep mode. Otherwise, the <b>Run-Mode Clock Gating Control (RCCGn)</b> registers are used when the controller enters a sleep mode.</p> <p>The <b>RCCGn</b> registers are always used to control the clocks in Run mode.</p> <p>This allows peripherals to consume less power when the controller is in a sleep mode and the peripheral is unused.</p>
26:23	SYSDIV	R/W	0xF	<p>System Clock Divisor</p> <p>Specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the <b>BYPASS</b> bit in this register is configured). See Table 5-3 on page 181 for bit encodings.</p> <p>If the <b>SYSDIV</b> value is less than <b>MINSYSDIV</b> (see page 210), and the PLL is being used, then the <b>MINSYSDIV</b> value is used as the divisor.</p> <p>If the PLL is not being used, the <b>SYSDIV</b> value can be less than <b>MINSYSDIV</b>.</p>
22	USESYSDIV	R/W	0	<p>Enable System Clock Divider</p> <p>Use the system clock divider as the source for the system clock. The system clock divider is forced to be used when the PLL is selected as the source.</p> <p>If the <b>USERCC2</b> bit in the <b>RCC2</b> register is set, then the <b>SYSDIV2</b> field in the <b>RCC2</b> register is used as the system clock divider rather than the <b>SYSDIV</b> field in this register.</p>
21	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
20	USEPWMDIV	R/W	0	Enable PWM Clock Divisor Use the PWM clock divisor as the source for the PWM clock.
19:17	PWMDIV	R/W	0x7	PWM Unit Clock Divisor This field specifies the binary divisor used to predive the system clock down for use as the timing reference for the PWM module. This clock is only power 2 divide and rising edge is synchronous without phase shift from the system clock.
				Value    Divisor
				0x0    /2
				0x1    /4
				0x2    /8
				0x3    /16
				0x4    /32
				0x5    /64
				0x6    /64
				0x7    /64 (default)
16:14	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	PWRDN	R/W	1	PLL Power Down This bit connects to the PLL PWRDN input. The reset value of 1 powers down the PLL.
12	reserved	RO	1	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	BYPASS	R/W	1	PLL Bypass Chooses whether the system clock is derived from the PLL output or the OSC source. If set, the clock that drives the system is the OSC source. Otherwise, the clock that drives the system is the PLL output clock divided by the system divider. See Table 5-3 on page 181 for programming guidelines.
				<b>Note:</b> The ADC must be clocked from the PLL or directly from a 14-MHz to 18-MHz clock source to operate properly. While the ADC works in a 14-18 MHz range, to maintain a 1 M sample/second rate, the ADC must be provided a 16-MHz clock source.

---

Bit/Field	Name	Type	Reset	Description																																																																								
10:6	XTAL	R/W	0xB	<p>Crystal Value</p> <p>This field specifies the crystal value attached to the main oscillator. The encoding for this field is provided below. Depending on the crystal used, the PLL frequency may not be exactly 400 MHz (see Table 23-10 on page 814 for more information).</p> <p>Frequencies that may be used with the USB interface are indicated in the table. 1	IOSCDIS	R/W	0	Internal Oscillator Disable 0: Internal oscillator (IOSC) is enabled. 1: Internal oscillator is disabled.										
0	MOSCDIS	R/W	1	Main Oscillator Disable 0: Main oscillator is enabled . 1: Main oscillator is disabled (default).										

## Register 9: XTAL to PLL Translation (PLLCFG), offset 0x064

This register provides a means of translating external crystal frequencies into the appropriate PLL settings. This register is initialized during the reset sequence and updated anytime that the **XTAL** field changes in the **Run-Mode Clock Configuration (RCC)** register (see page 196).

The PLL frequency is calculated using the **PLLCFG** field values, as follows:

$$\text{PLLFreq} = \text{OSCFreq} * F / (R + 1)$$

### XTAL to PLL Translation (PLLCFG)

Base 0x400F.E000

Offset 0x064

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31:14	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:5	F	RO	-	PLL F Value This field specifies the value supplied to the PLL's F input.
4:0	R	RO	-	PLL R Value This field specifies the value supplied to the PLL's R input.

## Register 10: GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C

This register controls which internal bus is used to access each GPIO port. When a bit is clear, the corresponding GPIO port is accessed across the legacy Advanced Peripheral Bus (APB) bus and through the APB memory aperture. When a bit is set, the corresponding port is accessed across the Advanced High-Performance Bus (AHB) bus and through the AHB memory aperture. Each GPIO port can be individually configured to use AHB or APB, but may be accessed only through one aperture. The AHB bus provides better back-to-back access performance than the APB bus. The address aperture in the memory map changes for the ports that are enabled for AHB access (see Table 9-3 on page 366).

### GPIO High-Performance Bus Control (GPIOHBCTL)

				Value Description
			1	Advanced High-Performance Bus (AHB)
			0	Advanced Peripheral Bus (APB). This bus is the legacy bus.
1	PORTB	R/W	0	Port B Advanced High-Performance Bus This bit defines the memory aperture for Port B.
				Value Description
			1	Advanced High-Performance Bus (AHB)
			0	Advanced Peripheral Bus (APB). This bus is the legacy bus.
0	PORTA	R/W	0	Port A Advanced High-Performance Bus This bit defines the memory aperture for Port A.
				Value Description
			1	Advanced High-Performance Bus (AHB)
			0	Advanced Peripheral Bus (APB). This bus is the legacy bus.

## Register 11: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields, as shown in Table 5-6, when the **USERCC2** bit is set, allowing the extended capabilities of the **RCC2** register to be used while also providing a means to be backward-compatible to previous parts. Each **RCC2** field that supersedes an **RCC** field is located at the same LSB bit position; however, some **RCC2** fields are larger than the corresponding **RCC** field.

**Table 5-6. RCC2 Fields that Override RCC fields**

RCC2 Field...	Overrides RCC Field
SYSDIV2, bits[28:23]	SYSDIV, bits[26:23]
PWRDN2, bit[13]	PWRDN, bit[13]
BYPASS2, bit[11]	BYPASS, bit[11]
OSCSRC2, bits[6:4]	OSCSRC, bits[5:4]

### Run-Mode Clock Configuration 2 (RCC2)

Base 0x400F.E000  
Offset 0x070  
Type R/W, reset 0x0780.6810

Bit/Field	Name	Type	Reset	Description
31	USERCC2	R/W	0	Use RCC2 When set, overrides the <b>RCC</b> register fields.
30:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28:23	SYSDIV2	R/W	0x0F	System Clock Divisor Specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the <b>BYPASS2</b> bit is configured). <b>SYSDIV2</b> is used for the divisor when both the <b>USESYSINV</b> bit in the <b>RCC</b> register and the <b>USERCC2</b> bit in this register are set. See Table 5-4 on page 181 for programming guidelines.
22:15	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	USBPWRDN	R/W	1	Power-Down USB PLL When set, powers down the USB PLL.
13	PWRDN2	R/W	1	Power-Down PLL When set, powers down the PLL.

Bit/Field	Name	Type	Reset	Description																		
12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.																		
11	BYPASS2	R/W	1	Bypass PLL When set, bypasses the PLL for the clock source. See Table 5-4 on page 181 for programming guidelines.																		
10:7	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0x3	30 kHz 30-kHz internal oscillator																					
0x4	Reserved																					
0x5	Reserved																					
0x6	Reserved																					
0x7	32 kHz 32.768-kHz external oscillator																					
3:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.																		

## Register 12: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock validation circuit. When enabled, this circuit monitors the energy on the MOSC pins to provide a Clock Valid signal. If the clock goes invalid after being enabled, the part does a hardware reset and reboots to the NMI handler.

### Main Oscillator Control (MOSCCTL)

Base 0x400F.E000  
Offset 0x07C  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	CVAL	R/W	0	Clock Validation for MOSC When set, the monitor circuit is enabled.

## Register 13: Deep Sleep Clock Configuration (DSLPCLKCFG), offset 0x144

This register provides configuration information for the hardware control of Deep Sleep Mode.

### Deep Sleep Clock Configuration (DSLPCLKCFG)

20	PWM	RO	1	PWM Module Present When set, indicates that the PWM module is present.
19:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	ADC	RO	1	ADC Module Present. When set, indicates that the ADC module is present.
15:12	MINSYSDIV	RO	0x3	System Clock Divider. Minimum 4-bit divider value for system clock. The reset value is hardware-dependent. See the <b>RCC</b> register for how to change the system clock divisor using the <b>SYSDIV</b> bit.
		Value	Description	
		0x3	Specifies a 50-MHz CPU clock with a PLL divider of 4.	
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	MAXADCSPD	RO	0x3	Max ADC Speed. This field indicates the maximum rate at which the ADC samples data.
		Value	Description	
		0x3	1M samples/second	
7	MPU	RO	1	MPU Present. When set, indicates that the Cortex-M3 Memory Protection Unit (MPU) module is present. See the "Cortex-M3 Peripherals" chapter in the Stellaris Data Sheet for details on the MPU.

Bit/Field	Name	Type	Reset	Description
6	HIB	RO	1	Hibernation Module Present. When set, indicates that the Hibernation module is present.
5	TEMPSNS	RO	1	Temp Sensor Present. When set, indicates that the on-chip temperature sensor is present.
4	PLL	RO	1	PLL Present. When set, indicates that the on-chip Phase Locked Loop (PLL) is present.
3	WDT	RO	1	Watchdog Timer Present. When set, indicates that a watchdog timer is present.
2	SWO	RO	1	SWO Trace Port Present. When set, indicates that the Serial Wire Output (SWO) trace port is present.
1	SWD	RO	1	SWD Present. When set, indicates that the Serial Wire Debugger (SWD) is present.
0	JTAG	RO	1	JTAG Present. When set, indicates that the JTAG debugger interface is present.

## Register 17: Device Capabilities 2 (DC2), offset 0x014

This register is predefined by the part and can be used to verify features.

Bit/Field	Name	Type	Reset	Description
31	32KHZ	RO	1	32KHz Input Clock Available. When set, indicates an even CCP pin is present and can be used as a 32-KHz input clock.
30	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
29	CCP5	RO	1	CCP5 Pin Present. When set, indicates that Capture/Compare/PWM pin 5 is present.
28	CCP4	RO	1	CCP4 Pin Present. When set, indicates that Capture/Compare/PWM pin 4 is present.
27	CCP3	RO	1	CCP3 Pin Present. When set, indicates that Capture/Compare/PWM pin 3 is present.
26	CCP2	RO	1	CCP2 Pin Present. When set, indicates that Capture/Compare/PWM pin 2 is present.
25	CCP1	RO	1	CCP1 Pin Present. When set, indicates that Capture/Compare/PWM pin 1 is present.
24	CCP0	RO	1	CCP0 Pin Present. When set, indicates that Capture/Compare/PWM pin 0 is present.
23	ADC7	RO	1	ADC7 Pin Present. When set, indicates that ADC pin 7 is present.
22	ADC6	RO	1	ADC6 Pin Present. When set, indicates that ADC pin 6 is present.
21	ADC5	RO	1	ADC5 Pin Present. When set, indicates that ADC pin 5 is present.
20	ADC4	RO	1	ADC4 Pin Present. When set, indicates that ADC pin 4 is present.
19	ADC3	RO	1	ADC3 Pin Present. When set, indicates that ADC pin 3 is present.
18	ADC2	RO	1	ADC2 Pin Present. When set, indicates that ADC pin 2 is present.
17	ADC1	RO	1	ADC1 Pin Present. When set, indicates that ADC pin 1 is present.
16	ADC0	RO	1	ADC0 Pin Present. When set, indicates that ADC pin 0 is present.

Bit/Field	Name	Type	Reset	Description
15	PWMFAULT	RO	1	PWM Fault Pin Present. When set, indicates that a PWM Fault pin is present. See <b>DC5</b> for specific Fault pins on this device.
14:11	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	C1PLUS	RO	1	C1+ Pin Present. When set, indicates that the analog comparator 1 (+) input pin is present.
9	C1MINUS	RO	1	C1- Pin Present. When set, indicates that the analog comparator 1 (-) input pin is present.
8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	C0PLUS	RO	1	C0+ Pin Present. When set, indicates that the analog comparator 0 (+) input pin is present.
6	C0MINUS	RO	1	C0- Pin Present. When set, indicates that the analog comparator 0 (-) input pin is present.
5	PWM5	RO	1	PWM5 Pin Present. When set, indicates that the PWM pin 5 is present.
4	PWM4	RO	1	PWM4 Pin Present. When set, indicates that the PWM pin 4 is present.
3	PWM3	RO	1	PWM3 Pin Present. When set, indicates that the PWM pin 3 is present.
2	PWM2	RO	1	PWM2 Pin Present. When set, indicates that the PWM pin 2 is present.
1	PWM1	RO	1	PWM1 Pin Present. When set, indicates that the PWM pin 1 is present.
0	PWM0	RO	1	PWM0 Pin Present. When set, indicates that the PWM pin 0 is present.

## Register 19: Device Capabilities 4 (DC4), offset 0x01C

This register is predefined by the part and can be used to verify features.

31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30	SW	RO	1	Software transfer on uDMA Ch30. When set, indicates uDMA channel 30 is available for software.
29:26	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
25	SSI1_TX	RO	1	SSI1 TX on uDMA Ch25. When set, indicates uDMA channel 25 is available and connected to the transmit path of SSI module 1.
24	SSI1_RX	RO	1	SSI1 RX on uDMA Ch24. When set, indicates uDMA channel 24 is available and connected to the receive path of SSI module 1.
23	UART1_TX	RO	1	UART1 TX on uDMA Ch23. When set, indicates uDMA channel 23 is available and connected to the transmit path of UART module 1.
22	UART1_RX	RO	1	UART1 RX on uDMA Ch22. When set, indicates uDMA channel 22 is available and connected to the receive path of UART module 1.
21:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	SSI0_TX	RO	1	SSI0 TX on uDMA Ch11. When set, indicates uDMA channel 11 is available and connected to the transmit path of SSI module 0.
10	SSI0_RX	RO	1	SSI0 RX on uDMA Ch10. When set, indicates uDMA channel 10 is available and connected to the receive path of SSI module 0.
9	UART0_TX	RO	1	UART0 TX on uDMA Ch9. When set, indicates uDMA channel 9 is available and connected to the transmit path of UART module 0.
8	UART0_RX	RO	1	UART0 RX on uDMA Ch8. When set, indicates uDMA channel 8 is available and connected to the receive path of UART module 0.

Bit/Field	Name	Type	Reset	Description
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	USB_EP3_TX	RO	1	USB EP3 TX on uDMA Ch5. When set, indicates uDMA channel 5 is available and connected to the transmit path of USB endpoint 3.
4	USB_EP3_RX	RO	1	USB EP3 RX on uDMA Ch4. When set, indicates uDMA channel 4 is available and connected to the receive path of USB endpoint 2.
3	USB_EP2_TX	RO	1	USB EP2 TX on uDMA Ch3. When set, indicates uDMA channel 3 is available and connected to the transmit path of USB endpoint 2.
2	USB_EP2_RX	RO	1	USB EP2 RX on uDMA Ch2. When set, indicates uDMA channel 1 is available and connected to the receive path of USB endpoint 2.
1	USB_EP1_TX	RO	1	USB EP1 TX on uDMA Ch1. When set, indicates uDMA channel 1 is available and connected to the transmit path of USB endpoint 1.
0	USB_EP1_RX	RO	1	USB EP1 RX on uDMA Ch0. When set, indicates uDMA channel 0 is available and connected to the receive path of USB endpoint 1.

## Register 23: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

### Run Mode Clock Gating Control Register 0 (RCGC0)

Base 0x400F.E000  
Offset 0x100  
Type R/W, reset 0x00000040

0x3	1M samples/second													
0x2	500K samples/second													
0x1	250K samples/second													
0x0	125K samples/second													
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
6	HIB	R/W	1	HIB Clock Gating Control. This bit controls the clock gating for the Hibernation module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled.										
5:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
3	WDT	R/W	0	WDT Clock Gating Control. This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, a read or write to the unit generates a bus fault.										
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										

## Register 24: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

3	WDT	R/W	0	WDT Clock Gating Control. This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, a read or write to the unit generates a bus fault.										
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										

## Register 25: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
31:21	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20	PWM	R/W	0	PWM Clock Gating Control. This bit controls the clock gating for the PWM module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, a read or write to the unit generates a bus fault.
19:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	ADC	R/W	0	ADC0 Clock Gating Control. This bit controls the clock gating for general SAR ADC module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, a read or write to the unit generates a bus fault.
15:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	HIB	R/W	1	HIB Clock Gating Control. This bit controls the clock gating for the Hibernation module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled.

Bit/Field	Name	Type	Reset	Description
5:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	WDT	R/W	0	WDT Clock Gating Control. This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, a read or write to the unit generates a bus fault.
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 26: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
31:26	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
25	COMP1	R/W	0	Analog Comparator 1 Clock Gating. This bit controls the clock gating for analog comparator 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
24	COMP0	R/W	0	Analog Comparator 0 Clock Gating. This bit controls the clock gating for analog comparator 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	Timer 3 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 3. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
18	TIMER2	R/W	0	Timer 2 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 2. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
17	TIMER1	R/W	0	Timer 1 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
16	TIMER0	R/W	0	Timer 0 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	R/W	0	I2C1 Clock Gating Control. This bit controls the clock gating for I2C module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control. This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
11:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	QEIO	R/W	0	QEIO Clock Gating Control. This bit controls the clock gating for QEI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Clock Gating Control. This bit controls the clock gating for SSI module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
4	SSI0	R/W	0	SSI0 Clock Gating Control. This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	UART1	R/W	0	UART1 Clock Gating Control. This bit controls the clock gating for UART module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
0	UART0	R/W	0	UART0 Clock Gating Control. This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

## Register 27: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DGCG1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

25	COMP1	R/W	0	Analog Comparator 1 Clock Gating. This bit controls the clock gating for analog comparator 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
24	COMP0	R/W	0	Analog Comparator 0 Clock Gating. This bit controls the clock gating for analog comparator 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	Timer 3 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 3. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
18	TIMER2	R/W	0	Timer 2 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 2. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
17	TIMER1	R/W	0	Timer 1 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
16	TIMER0	R/W	0	Timer 0 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	R/W	0	I2C1 Clock Gating Control. This bit controls the clock gating for I2C module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control. This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
11:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	QEIO	R/W	0	QEIO Clock Gating Control. This bit controls the clock gating for QEI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Clock Gating Control. This bit controls the clock gating for SSI module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
4	SSI0	R/W	0	SSI0 Clock Gating Control. This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	UART1	R/W	0	UART1 Clock Gating Control. This bit controls the clock gating for UART module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
0	UART0	R/W	0	UART0 Clock Gating Control. This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

## Register 28: Deep Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

31:26	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
25	COMP1	R/W	0	Analog Comparator 1 Clock Gating. This bit controls the clock gating for analog comparator 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
24	COMP0	R/W	0	Analog Comparator 0 Clock Gating. This bit controls the clock gating for analog comparator 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	Timer 3 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 3. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
18	TIMER2	R/W	0	Timer 2 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 2. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
17	TIMER1	R/W	0	Timer 1 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
16	TIMER0	R/W	0	Timer 0 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	R/W	0	I2C1 Clock Gating Control. This bit controls the clock gating for I2C module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control. This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
11:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	QEIO	R/W	0	QEIO Clock Gating Control. This bit controls the clock gating for QEI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Clock Gating Control. This bit controls the clock gating for SSI module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
4	SSI0	R/W	0	SSI0 Clock Gating Control. This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	UART1	R/W	0	UART1 Clock Gating Control. This bit controls the clock gating for UART module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
0	UART0	R/W	0	UART0 Clock Gating Control. This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

## Register 29: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	USBO	R/W	0	USB0 Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
15:14	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	UDMA	R/W	0	UDMA Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
12:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	GPIOH	R/W	0	Port H Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
6	GPIOG	R/W	0	Port G Clock Gating Control. This bit controls the clock gating for Port G. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
5	GPIOF	R/W	0	Port F Clock Gating Control. This bit controls the clock gating for Port F. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
4	GPIOE	R/W	0	Port E Clock Gating Control. This bit controls the clock gating for Port E. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3	GPIOD	R/W	0	Port D Clock Gating Control. This bit controls the clock gating for Port D. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
2	GPIOC	R/W	0	Port C Clock Gating Control. This bit controls the clock gating for Port C. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
1	GPIOB	R/W	0	Port B Clock Gating Control. This bit controls the clock gating for Port B. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
0	GPIOA	R/W	0	Port A Clock Gating Control. This bit controls the clock gating for Port A. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

## Register 30: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

16	USB0	R/W	0	USB0 Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
15:14	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	UDMA	R/W	0	UDMA Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
12:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	GPIOH	R/W	0	Port H Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
6	GPIOG	R/W	0	Port G Clock Gating Control. This bit controls the clock gating for Port G. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
5	GPIOF	R/W	0	Port F Clock Gating Control. This bit controls the clock gating for Port F. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
4	GPIOE	R/W	0	Port E Clock Gating Control. This bit controls the clock gating for Port E. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3	GPIOD	R/W	0	Port D Clock Gating Control. This bit controls the clock gating for Port D. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
2	GPIOC	R/W	0	Port C Clock Gating Control. This bit controls the clock gating for Port C. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
1	GPIOB	R/W	0	Port B Clock Gating Control. This bit controls the clock gating for Port B. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
0	GPIOA	R/W	0	Port A Clock Gating Control. This bit controls the clock gating for Port A. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

## Register 31: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## 6 Hibernation Module

The Hibernation Module manages removal and restoration of power to provide a means for reducing power consumption. When the processor and peripherals are idle, power can be completely removed with only the Hibernation module remaining powered. Power can be restored based on an external signal, or at a certain time using the built-in Real-Time Clock (RTC). The Hibernation module can be independently supplied from a battery or an auxiliary power supply.

The Hibernation module has the following features:

- System power control using discrete external regulator
- Dedicated pin for waking from an external signal
- Low-battery detection, signaling, and interrupt generation
- 32-bit real-time clock (RTC)
- Two 32-bit RTC match registers for timed wake-up and interrupt generation
- Clock source from a 32.768-kHz external oscillator or a 4.194304-MHz crystal
- RTC predivider trim for making fine adjustments to the clock rate
- 64 32-bit words of non-volatile memory
- Programmable interrupts for RTC match, external wake, and low battery events

## 6.1 Block Diagram

Figure 6-1. Hibernation Module Block Diagram

## 6.2 Functional Description

The Hibernation module controls the power to the processor with an enable signal ( $\overline{\text{HIB}}$ ) that signals an external voltage regulator to turn off.

The Hibernation module power source is determined dynamically. The supply voltage of the Hibernation module is the larger of the main voltage source ( $V_{DD}$ ) or the battery/auxiliary voltage source ( $V_{BAT}$ ). A voting circuit indicates the larger and an internal power switch selects the appropriate voltage source. The Hibernation module also has a separate clock source to maintain a real-time clock (RTC). Once in hibernation, the module signals an external voltage regulator to turn back on the power when an external pin ( $\overline{\text{WAKE}}$ ) is asserted, or when the internal RTC reaches a certain value. The Hibernation module can also detect when the battery voltage is low, and optionally prevent hibernation when this occurs.

When waking from hibernation, the  $\overline{\text{HIB}}$  signal is deasserted. The return of  $V_{DD}$  causes a POR to be executed. The time from when the  $\overline{\text{WAKE}}$  signal is asserted to when code begins execution is equal to the wake-up time ( $t_{\text{WAKE\_TO\_HIB}}$ ) plus the power-on reset time ( $T_{\text{IRPOR}}$ ).

### 6.2.1 Register Access Timing

Because the Hibernation module has an independent clocking domain, certain registers must be written only with a timing gap between accesses. The delay time is  $t_{\text{HIB\_REG\_WRITE}}$ , therefore software must guarantee that a delay of  $t_{\text{HIB\_REG\_WRITE}}$  is inserted between back-to-back writes to certain Hibernation registers, or between a write followed by a read to those same registers. There is no restriction on timing for back-to-back reads from the Hibernation module. Software may make use

of the WRC bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **HIBCTL** for WRC=1 prior to accessing any affected register. The following registers are subject to this timing restriction:

- **Hibernation RTC Counter (HIBRTCC)**
- **Hibernation RTC Match 0 (HIBRTCM0)**
- **Hibernation RTC Match 1 (HIBRTCM1)**
- **Hibernation RTC Load (HIBRTCLD)**
- **Hibernation RTC Trim (HIBRTCT)**
- **Hibernation Data (HIBDATA)**

### 6.2.2 Clock Source

The Hibernation module must be clocked by an external source, even if the RTC feature is not used. An external oscillator or crystal can be used for this purpose. To use a crystal, a 4.194304-MHz crystal is connected to the **XOSC0** and **XOSC1** pins. This clock signal is divided by 128 internally to produce the 32.768-kHz clock reference. For an alternate clock source, a 32.768-kHz oscillator can be connected to the **XOSC0** pin. See Figure 6-2 on page 250 and Figure 6-3 on page 250. Note that these diagrams only show the connection to the Hibernation pins and not to the full system. See “Hibernation Module” on page 818 for specific values.

The clock source is enabled by setting the **CLK32EN** bit of the **HIBCTL** register. The type of clock source is selected by setting the **CLKSEL** bit to 0 for a 4.194304-MHz clock source, and to 1 for a 32.768-kHz clock source. If the bit is set to 0, the 4.194304-MHz input clock is divided by 128, resulting in a 32.768-kHz clock source. If a crystal is used for the clock source, the software must leave a delay of  $t_{XOSC\_SETTLE}$  after setting the **CLK32EN** bit and before any other accesses to the Hibernation module registers. The delay allows the crystal to power up and stabilize. If an oscillator is used for the clock source, no delay is needed.

**Figure 6-2. Clock Source Using Crystal**

**Note:**  $X_1$  = Crystal frequency is  $f_{XOSC\_XTAL}$ .

$C_{1,2}$  = Capacitor value derived from crystal vendor load capacitance specifications.

$R_L$  = Load resistor is  $R_{XOSC\_LOAD}$ .

$R_{PU}$  = Pull-up resistor (1 M $\frac{1}{2}$ ).

See "Hibernation Module" on page 818 for specific parameter values.

**Figure 6-3. Clock Source Using Dedicated Oscillator**

**Note:**  $R_{PU}$  = Pull-up resistor (1 M $\frac{1}{2}$ ).

### 6.2.3 Battery Management

The Hibernation module can be independently powered by a battery or an auxiliary power source. The module can monitor the voltage level of the battery and detect when the voltage drops below  $V_{LOWBAT}$ . When this happens, an interrupt can be generated. The module can also be configured so that it will not go into Hibernate mode if the battery voltage drops below this threshold. Battery voltage is not measured while in Hibernate mode.

---

**Important:** System level factors may affect the accuracy of the low battery detect circuit. The designer should consider battery type, discharge characteristics, and a test load during battery voltage measurements.

Note that the Hibernation module draws power from whichever source ( $V_{BAT}$  or  $V_{DD}$ ) has the higher voltage. Therefore, it is important to design the circuit to ensure that  $V_{DD}$  is higher than  $V_{BAT}$  under nominal conditions or else the Hibernation module draws power from the battery even when  $V_{DD}$  is available.

The Hibernation module can be configured to detect a low battery condition by setting the `LOWBATEN` bit of the **HIBCTL** register. In this configuration, the `LOWBAT` bit of the **HIBRIS** register will be set when the battery level is low. If the `VABORT` bit is also set, then the module is prevented from entering Hibernation mode when a low battery is detected. The module can also be configured to generate an interrupt for the low-battery condition (see “Interrupts and Status” on page 252).

#### 6.2.4 Real-Time Clock

The Hibernation module includes a 32-bit counter that increments once per second with a proper clock source and configuration (see “Clock Source” on page 249). The 32.768-kHz clock signal is fed into a predivider register which counts down the 32.768-kHz clock ticks to achieve a once per second clock rate for the RTC. The rate can be adjusted to compensate for inaccuracies in the clock source by using the predivider trim register, **HIBRTCT**. This register has a nominal value of 0xFFFF, and is used for one second out of every 64 seconds to divide the input clock. This allows the software to make fine corrections to the clock rate by adjusting the predivider trim register up or down from 0xFFFF. The predivider trim should be adjusted up from 0xFFFF in order to slow down the RTC rate, and down from 0xFFFF in order to speed up the RTC rate.

The Hibernation module includes two 32-bit match registers that are compared to the value of the RTC counter. The match registers can be used to wake the processor from hibernation mode, or to generate an interrupt to the processor if it is not in hibernation.

The RTC must be enabled with the `RTCEN` bit of the **HIBCTL** register. The value of the RTC can be set at any time by writing to the **HIBRTCLD** register. The predivider trim can be adjusted by reading and writing the **HIBRTCT** register. The predivider uses this register once every 64 seconds to adjust the clock rate. The two match registers can be set by writing to the **HIBRTCM0** and **HIBRTCM1** registers. The RTC can be configured to generate interrupts by using the interrupt registers (see “Interrupts and Status” on page 252).

#### 6.2.5 Non-Volatile Memory

The Hibernation module contains 64 32-bit words of memory which are retained during hibernation. This memory is powered from the battery or auxiliary power supply during hibernation. The processor software can save state information in this memory prior to hibernation, and can then recover the state upon waking. The non-volatile memory can be accessed through the **HIBDATA** registers.

#### 6.2.6 Power Control

---

**Important:** The Hibernation Module requires special system implementation considerations when using  $\overline{HIB}$  to control power, as it is intended to power-down all other sections of its host device. All system signals and power supplies that connect to the chip must be driven to 0 V<sub>DC</sub> or powered down with the same regulator controlled by  $\overline{HIB}$ . See “Hibernation Module” on page 818 for more details.

The Hibernation module controls power to the microcontroller through the use of the  $\overline{HIB}$  pin. This pin is intended to be connected to the enable signal of the external regulator(s) providing 3.3 V

and/or 2.5 V to the microcontroller. When the  $\overline{\text{HIB}}$  signal is asserted by the Hibernation module, the external regulator is turned off and no longer powers the system. The Hibernation module remains powered from the  $V_{\text{BAT}}$  supply (which could be a battery or an auxiliary power source) until a Wake event. Power to the device is restored by deasserting the  $\overline{\text{HIB}}$  signal, which causes the external regulator to turn power back on to the chip.

### 6.2.7 Initiating Hibernate

Hibernation mode is initiated by the microcontroller setting the  $\text{HIBREQ}$  bit of the **HIBCTL** register. Prior to doing this, a wake-up condition must be configured, either from the external  $\overline{\text{WAKE}}$  pin, or by using an RTC match.

The Hibernation module is configured to wake from the external  $\overline{\text{WAKE}}$  pin by setting the  $\text{PINWEN}$  bit of the **HIBCTL** register. It is configured to wake from RTC match by setting the  $\text{RTCWEN}$  bit. Either one or both of these bits can be set prior to going into hibernation. The  $\overline{\text{WAKE}}$  pin includes a weak internal pull-up. Note that both the  $\text{HIB}$  and  $\overline{\text{WAKE}}$  pins use the Hibernation module's internal power supply as the logic 1 reference.

When the Hibernation module wakes, the microcontroller will see a normal power-on reset. Software can detect that the power-on was due to a wake from hibernation by examining the raw interrupt status register (see “Interrupts and Status” on page 252) and by looking for state data in the non-volatile memory (see “Non-Volatile Memory” on page 251).

When the  $\overline{\text{HIB}}$  signal deasserts, enabling the external regulator, the external regulator must reach the operating voltage within  $t_{\text{HIB\_TO\_VDD}}$ .

### 6.2.8 Interrupts and Status

The Hibernation module can generate interrupts when the following conditions occur:

- Assertion of  $\overline{\text{WAKE}}$  pin
- RTC match
- Low battery detected

All of the interrupts are ORed together before being sent to the interrupt controller, so the Hibernation module can only generate a single interrupt request to the controller at any given time. The software interrupt handler can service multiple interrupt events by reading the **HIBMIS** register. Software can also read the status of the Hibernation module at any time by reading the **HIBRIS** register which shows all of the pending events. This register can be used at power-on to see if a wake condition is pending, which indicates to the software that a hibernation wake occurred.

The events that can trigger an interrupt are configured by setting the appropriate bits in the **HIBIM** register. Pending interrupts can be cleared by writing the corresponding bit in the **HIBIC** register.

## 6.3 Initialization and Configuration

The Hibernation module can be set in several different configurations. The following sections show the recommended programming sequence for various scenarios. The examples below assume that a 32.768-kHz oscillator is used, and thus always show bit 2 ( $\text{CLKSEL}$ ) of the **HIBCTL** register set to 1. If a 4.194304-MHz crystal is used instead, then the  $\text{CLKSEL}$  bit remains cleared. Because the Hibernation module runs at 32.768 kHz and is asynchronous to the rest of the system, software must allow a delay of  $t_{\text{HIB\_REG\_WRITE}}$  after writes to certain registers (see “Register Access Timing” on page 248). The registers that require a delay are listed in a note in “Register Map” on page 254 as well as in each register description.

### 6.3.1 Initialization

The Hibernation module clock source must be enabled first, even if the RTC feature is not used. If a 4.194304-MHz crystal is used, perform the following steps:

1. Write 0x40 to the **HIBCTL** register at offset 0x10 to enable the crystal and select the divide-by-128 input path.
2. Wait for a time of  $t_{XOSC\_SETTLE}$  for the crystal to power up and stabilize before performing any other operations with the Hibernation module.

If a 32.678-kHz oscillator is used, then perform the following steps:

1. Write 0x44 to the **HIBCTL** register at offset 0x10 to enable the oscillator input.
2. No delay is necessary.

The above is only necessary when the entire system is initialized for the first time. If the processor is powered due to a wake from hibernation, then the Hibernation module has already been powered up and the above steps are not necessary. The software can detect that the Hibernation module and clock are already powered by examining the **CLK32EN** bit of the **HIBCTL** register.

### 6.3.2 RTC Match Functionality (No Hibernation)

Use the following steps to implement the RTC match functionality of the Hibernation module:

1. Write the required RTC match value to one of the **HIBRTCMn** registers at offset 0x004 or 0x008.
2. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C.
3. Set the required RTC match interrupt mask in the **RTCALT0** and **RTCALT1** bits (bits 1:0) in the **HIBIM** register at offset 0x014.
4. Write 0x0000.0041 to the **HIBCTL** register at offset 0x010 to enable the RTC to begin counting.

### 6.3.3 RTC Match/Wake-Up from Hibernation

Use the following steps to implement the RTC match and wake-up functionality of the Hibernation module:

1. Write the required RTC match value to the **HIBRTCMn** registers at offset 0x004 or 0x008.
2. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C.
3. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x12C.
4. Set the RTC Match Wake-Up and start the hibernation sequence by writing 0x0000.004F to the **HIBCTL** register at offset 0x010.

### 6.3.4 External Wake-Up from Hibernation

Use the following steps to implement the Hibernation module with the external **WAKE** pin as the wake-up source for the microcontroller:

1. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x12C.

2. Enable the external wake and start the hibernation sequence by writing 0x0000.0056 to the **HIBCTL** register at offset 0x010.

### 6.3.5 RTC/External Wake-Up from Hibernation

1. Write the required RTC match value to the **HIBRTCMn** registers at offset 0x004 or 0x008.
2. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C.
3. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x12C.
4. Set the RTC Match/External Wake-Up and start the hibernation sequence by writing 0x0000.005F to the **HIBCTL** register at offset 0x010.

### 6.3.6 Register Reset

The Hibernation module handles resets according to the following conditions:

- Cold Reset

When the hibernation module has no externally applied voltage and detects a change to either  $V_{DD}$  or  $V_{BAT}$ , it resets all hibernation module registers to the value in Table 6-1 on page 255.

- Reset During Hibernation Module Disable

When the module has either not been enabled or has been disabled by software, the reset is passed through to the Hibernation module circuitry, and the internal state of the module is reset.

- Reset While Hibernation Module is in Hibernation Mode

While in Hibernation mode, or while transitioning from Hibernation mode to run mode (leaving the power cut), the reset generated by the POR circuitry of the device is suppressed, and the state of the Hibernation module's registers is unaffected.

- Reset While Hibernation Module is in Normal Mode

While in normal mode (not hibernating), any reset is suppressed if either the **RTCEN** or the **PINWEN** bit is set in the **HIBCTL** register, and the content/state of the control and data registers is unaffected.

Software must initialize any control or data registers in this condition. Therefore, software is the only mechanism to enable or disable the oscillator and real-time clock operation, or to clear contents of the data memory. The only state that must be cleared by a reset operation while not in Hibernation mode is any state that prevents software from managing the interface.

**Note:** If  $V_{DD}$  drops below operational range while in normal mode (not hibernating), all hibernation module registers are reset to the value in Table 6-1 on page 255, regardless of whether the proper voltage is applied to  $V_{BAT}$ .

## 6.4 Register Map

Table 6-1 on page 255 lists the Hibernation registers. All addresses given are relative to the Hibernation Module base address at 0x400F.C000. Note that the Hibernation module clock must be enabled before the registers can be programmed (see page 222). There must be a delay of 3 system clocks after the Hibernation module clock is enabled before any Hibernation module registers are accessed.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software

should make use of the WRC bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

**Table 6-1. Hibernation Module Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	HIBRTCC	RO	0x0000.0000	Hibernation RTC Counter	256
0x004	HIBRTCM0	R/W	0xFFFF.FFFF	Hibernation RTC Match 0	257
0x008	HIBRTCM1	R/W	0xFFFF.FFFF	Hibernation RTC Match 1	258
0x00C	HIBRTCLD	R/W	0xFFFF.FFFF	Hibernation RTC Load	259
0x010	HIBCTL	R/W	0x8000.0000	Hibernation Control	260
0x014	HIBIM	R/W	0x0000.0000	Hibernation Interrupt Mask	263
0x018	HIBRIS	RO	0x0000.0000	Hibernation Raw Interrupt Status	264
0x01C	HIBMIS	RO	0x0000.0000	Hibernation Masked Interrupt Status	265
0x020	HIBIC	R/W1C	0x0000.0000	Hibernation Interrupt Clear	266
0x024	HIBRTCT	R/W	0x0000.7FFF	Hibernation RTC Trim	267
0x030-0x12C	HIBDATA	R/W	-	Hibernation Data	268

## 6.5 Register Descriptions

The remainder of this section lists and describes the Hibernation module registers, in numerical order by address offset.

## Register 1: Hibernation RTC Counter (HIBRTCC), offset 0x000

This register is the current 32-bit value of the RTC counter.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

### Hibernation RTC Counter (HIBRTCC)

Base 0x400F.C000

Offset 0x000

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	RTCC	RO	0x0000.0000	RTC Counter A read returns the 32-bit counter value. This register is read-only. To change the value, use the <b>HIBRTCLD</b> register.

## Register 2: Hibernation RTC Match 0 (HIBRTCM0), offset 0x004

This register is the 32-bit match 0 register for the RTC counter.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

### Hibernation RTC Match 0 (HIBRTCM0)

Base 0x400F.C000

Offset 0x004

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	RTCM0	R/W	0xFFFF.FFFF	RTC Match 0 A write loads the value into the RTC match register. A read returns the current match value.

### Register 3: Hibernation RTC Match 1 (HIBRTCM1), offset 0x008

This register is the 32-bit match 1 register for the RTC counter.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

#### Hibernation RTC Match 1 (HIBRTCM1)

Base 0x400F.C000

Offset 0x008

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	RTCM1	R/W	0xFFFF.FFFF	RTC Match 1 A write loads the value into the RTC match register. A read returns the current match value.

## Register 4: Hibernation RTC Load (HIBRTCLD), offset 0x00C

This register is the 32-bit value loaded into the RTC counter.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

### Hibernation RTC Load (HIBRTCLD)

Base 0x400F.C000

Offset 0x00C

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	RTCLD	R/W	0xFFFF.FFFF	RTC Load A write loads the current value into the RTC counter (RTCC). A read returns the 32-bit load value.

## Register 5: Hibernation Control (HIBCTL), offset 0x010

This register is the control register for the Hibernation module.

### Hibernation Control (HIBCTL)

Base 0x400F.C000  
Offset 0x010  
Type R/W, reset 0x8000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description						
31	WRC	RO	1	<p>Write Complete/Capable</p> <p>This bit indicates whether the hibernation module can receive a write operation.</p>						
				<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>The interface is processing a prior write and is busy. Any write operation that is attempted while WRC=0 results in undetermined behavior.</td> </tr> <tr> <td>1</td> <td>The interface is ready to accept a write.</td> </tr> </tbody> </table>	Value	Description	0	The interface is processing a prior write and is busy. Any write operation that is attempted while WRC=0 results in undetermined behavior.	1	The interface is ready to accept a write.
Value	Description									
0	The interface is processing a prior write and is busy. Any write operation that is attempted while WRC=0 results in undetermined behavior.									
1	The interface is ready to accept a write.									
				<p>Software must poll this bit between write requests and defer writes until WRC=1 to ensure proper operation.</p> <p>This difference may be exploited by software at reset time to detect which method of programming is appropriate: 0 = software delay loops required; 1 = WRC paced available.</p> <p>The bit name WRC means "Write Complete," which is the normal use of the bit (between write accesses). However, because the bit is set out-of-reset, the name can also mean "Write Capable" which simply indicates that the interface may be written to by software. This meaning also has more meaning to the out-of-reset sense.</p>						
30:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
7	VABORT	R/W	0	<p>Power Cut Abort Enable</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Power cut occurs during a low-battery alert.</td> </tr> <tr> <td>1</td> <td>Power cut is aborted.</td> </tr> </tbody> </table>	Value	Description	0	Power cut occurs during a low-battery alert.	1	Power cut is aborted.
Value	Description									
0	Power cut occurs during a low-battery alert.									
1	Power cut is aborted.

## Register 7: Hibernation Raw Interrupt Status (HIBRIS), offset 0x018

This register is the raw interrupt status for the Hibernation module interrupt sources.

### Hibernation Raw Interrupt Status (HIBRIS)

Base 0x400F.C000  
Offset 0x018  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EXTW	RO	0	External Wake-Up Raw Interrupt Status
2	LOWBAT	RO	0	Low Battery Voltage Raw Interrupt Status
1	RTCAWT1	RO	0	RTC Alert1 Raw Interrupt Status
0	RTCAWT0	RO	0	RTC Alert0 Raw Interrupt Status

## Register 8: Hibernation Masked Interrupt Status (HIBMIS), offset 0x01C

This register is the masked interrupt status for the Hibernation module interrupt sources.

### Hibernation Masked Interrupt Status (HIBMIS)

Base 0x400F.C000  
Offset 0x01C  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EXTW	RO	0	External Wake-Up Masked Interrupt Status
2	LOWBAT	RO	0	Low Battery Voltage Masked Interrupt Status
1	RTCALT1	RO	0	RTC Alert1 Masked Interrupt Status
0	RTCALT0	RO	0	RTC Alert0 Masked Interrupt Status

## Register 9: Hibernation Interrupt Clear (HIBIC), offset 0x020

This register is the interrupt write-one-to-clear register for the Hibernation module interrupt sources.

### Hibernation Interrupt Clear (HIBIC)

Base 0x400F.C000  
Offset 0x020  
Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EXTW	R/W1C	0	External Wake-Up Masked Interrupt Clear Reads return an indeterminate value.
2	LOWBAT	R/W1C	0	Low Battery Voltage Masked Interrupt Clear Reads return an indeterminate value.
1	RTCACT1	R/W1C	0	RTC Alert1 Masked Interrupt Clear Reads return an indeterminate value.
0	RTCACT0	R/W1C	0	RTC Alert0 Masked Interrupt Clear Reads return an indeterminate value.

## Register 10: Hibernation RTC Trim (HIBRTCT), offset 0x024

This register contains the value that is used to trim the RTC clock predivider. It represents the computed underflow value that is used during the trim cycle. It is represented as  $0x7FFF \pm N$  clock cycles.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

### Hibernation RTC Trim (HIBRTCT)

Base 0x400F.C000  
Offset 0x024  
Type R/W, reset 0x0000.7FFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TRIM	R/W	0x7FFF	RTC Trim Value This value is loaded into the RTC predivider every 64 seconds. It is used to adjust the RTC rate to account for drift and inaccuracy in the clock source. The compensation is made by software by adjusting the default value of 0x7FFF up or down.

## Register 11: Hibernation Data (HIBDATA), offset 0x030-0x12C

This address space is implemented as a 64x32-bit memory (256 bytes). It can be loaded by the system processor in order to store any non-volatile state data and will not lose power during a power cut operation.

**Note:** **HIBRTCC**, **HIBRTCM0**, **HIBRTCM1**, **HIBRTCLD**, **HIBRTCT**, and **HIBDATA** are on the Hibernation module clock domain and have special timing requirements. Software should make use of the WRC bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. See “Register Access Timing” on page 248.

### Hibernation Data (HIBDATA)

# 7 Internal Memory

The LM3S3748 microcontroller comes with 64 KB of bit-banded SRAM and 128 KB of flash memory. The flash controller provides a user-friendly interface, making flash programming a simple task. Flash protection can be applied to the flash memory on a 2-KB block basis.

## 7.1 Block Diagram

Figure 7-1 on page 269 illustrates the Flash functions. The dashed boxes in the figure indicate registers residing in the System Control module rather than the Flash Control module.

**Figure 7-1. Flash Block Diagram**

## 7.2 Functional Description

This section describes the functionality of the SRAM, ROM, and Flash memories.

### 7.2.1 SRAM Memory

**Note:** The SRAM memory is implemented using two 32-bit wide SRAM banks (separate SRAM arrays). The banks are partitioned so that one bank contains all even words (the even bank) and the other contains all odd words (the odd bank). A write access that is followed immediately by a read access to the same bank will incur a stall of a single clock cycle. However, a write to one bank followed by a read of the other bank can occur in successive clock cycles without incurring any delay.

The internal SRAM of the Stellaris® devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

The bit-band alias is calculated by using the formula:

```
bit-band alias = bit-band base + (byte offset * 32) + (bit number * 4)
```

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

```
0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C
```

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, see “Bit-Banding” on page 78.

## 7.2.2 ROM Memory

The ROM of the Stellaris device is located at address 0x0100.0000 of the device memory map and contains the following components:

- Stellaris Boot Loader and vector table (see “Boot Loader” on page 825)
- Stellaris Peripheral Driver Library (DriverLib) release for product-specific peripherals and interfaces (see “ROM DriverLib Functions” on page 830)

## 7.2.3 Flash Memory

The flash is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. An individual 32-bit word can be programmed to change bits that are currently 1 to a 0. These blocks are paired into a set of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

### 7.2.3.1 Flash Memory Timing

The timing for the flash is automatically handled by the flash controller. However, in order to do so, it must know the clock rate of the system in order to time its internal signals properly. The number of clock cycles per microsecond must be provided to the flash controller for it to accomplish this timing. It is software's responsibility to keep the flash controller updated with this information via the **USec Reload (USECRL)** register.

On reset, the **USECRL** register is loaded with a value that configures the flash timing so that it works with the maximum clock rate of the part. If software changes the system operating frequency, the new operating frequency minus 1 (in MHz) must be loaded into **USECRL** before any flash modifications are attempted. For example, if the device is operating at a speed of 20 MHz, a value of 0x13 (20-1) must be written to the **USECRL** register.

### 7.2.3.2 Flash Memory Protection

The user is provided two forms of flash protection per 2-KB flash blocks in two pairs of 32-bit wide registers. The protection policy for each form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn):** If set, the block may be programmed (written) or erased. If cleared, the block may not be changed.
- **Flash Memory Protection Read Enable (FMPREn):** If a bit is set, the corresponding block may be executed or read by software or debuggers. If a bit is cleared, the corresponding block may only be executed, and contents of the memory block are prohibited from being read as data.

The policies may be combined as shown in Table 7-1 on page 271.

**Table 7-1. Flash Protection Policy Combinations**

FMPPEn	FMPREn	Protection
0	0	Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.
1	0	The block may be written, erased or executed, but not read. This combination is unlikely to be used.
0	1	Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access.
1	1	No protection. The block may be written, erased, executed or read.

A Flash memory access that attempts to read a read-protected block (**FMPREn** bit is set) is prohibited and generates a bus fault. A Flash memory access that attempts to program or erase a program-protected block (**FMPPEn** bit is set) is prohibited and can optionally generate an interrupt (by setting the **AMASK** bit in the **Flash Controller Interrupt Mask (FCIM)** register) to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. These settings create a policy of open access and programmability. The register bits may be changed by clearing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The changes are committed using the **Flash Memory Control (FMC)** register. Details on programming these bits are discussed in “Nonvolatile Register Programming” on page 272.

### 7.2.3.3 Interrupts

The Flash memory controller can generate interrupts when the following conditions are observed:

- Programming Interrupt - signals when a program or erase action is complete.
- Access Interrupt - signals when a program or erase action has been attempted on a 2-kB block of memory that is protected by its corresponding **FMPPEn** bit.

The interrupt events that can trigger a controller-level interrupt are defined in the **Flash Controller Masked Interrupt Status (FCMIS)** register (see page 281) by setting the corresponding **MASK** bits. If interrupts are not used, the raw interrupt status is always visible via the **Flash Controller Raw Interrupt Status (FCRIS)** register (see page 280).

Interrupts are always cleared (for both the **FCMIS** and **FCRIS** registers) by writing a 1 to the corresponding bit in the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register (see page 282).

## 7.3 Flash Memory Initialization and Configuration

### 7.3.1 Flash Programming

The Stellaris devices provide a user-friendly interface for flash programming. All erase/program operations are handled via three registers: **FMA**, **FMD**, and **FMC**.

During a Flash memory operation (write, page erase, or mass erase) access to the Flash memory is inhibited. As a result, instruction and literal fetches are held off until the Flash memory operation is complete. If instruction execution is required during a Flash memory operation, the code that is executing must be placed in SRAM and executed from there while the flash operation is in progress.

#### 7.3.1.1 To program a 32-bit word

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the flash write key and the `WRITE` bit (a value of 0xA442.0001) to the **FMC** register.
4. Poll the **FMC** register until the `WRITE` bit is cleared.

#### 7.3.1.2 To perform an erase of a 1-KB page

1. Write the page address to the **FMA** register.
2. Write the flash write key and the `ERASE` bit (a value of 0xA442.0002) to the **FMC** register.
3. Poll the **FMC** register until the `ERASE` bit is cleared.

#### 7.3.1.3 To perform a mass erase of the flash

1. Write the flash write key and the `MERASE` bit (a value of 0xA442.0004) to the **FMC** register.
2. Poll the **FMC** register until the `MERASE` bit is cleared.

### 7.3.2 Nonvolatile Register Programming

This section discusses how to update registers that are resident within the Flash memory itself. These registers exist in a separate space from the main Flash memory array and are not affected by an ERASE or MASS ERASE operation. The bits in these registers can be changed from 1 to 0 with a write operation. Prior to being committed, the register contents are unaffected by any reset condition except power-on reset, which returns the register contents to the original value. By committing the register values using the `COMT` bit in the **FMC** register, the register contents become nonvolatile and are therefore retained following power cycling. Once the register contents are committed, the only way to restore the factory default values is to perform the sequence described in the section called "Recovering a "Locked" Device" on page 166.

With the exception of the **USER\_DBG** register, the settings in these registers can be tested before committing them to Flash memory. For the **USER\_DBG** register, the data to be written is loaded into the **FMD** register before it is committed. The **FMD** register is read only and does not allow the **USER\_DBG** operation to be tried before committing it to nonvolatile memory.

**Important:** The Flash memory resident registers can only have bits changed from 1 to 0 by user programming and can only be committed once. After being committed, these registers can only be restored to their factory default values only by performing the sequence described in the section called “Recovering a “Locked” Device” on page 166. The mass erase of the main Flash memory array caused by the sequence is performed prior to restoring these registers.

In addition, the **USER\_REG0**, **USER\_REG1**, **USER\_REG2**, **USER\_REG3**, and **USER\_DBG** registers each use bit 31 (**NW**) to indicate that they have not been committed and bits in the register may be changed from 1 to 0. Table 7-2 on page 273 provides the **FMA** address required for commitment of each of the registers and the source of the data to be written when the **FMC** register is written with a value of 0xA442.0008. After writing the **COMT** bit, the user may poll the **FMC** register to wait for the commit operation to complete.

**Table 7-2. User-Programmable Flash Memory Resident Registers**

Register to be Committed	FMA Value	Data Source
FMPRE0	0x0000.0000	FMPRE0
FMPRE1	0x0000.0002	FMPRE1
FMPPE0	0x0000.0001	FMPPE0
FMPPE1	0x0000.0003	FMPPE1
USER_REG0	0x8000.0000	USER_REG0
USER_REG1	0x8000.0001	USER_REG1
USER_REG2	0x8000.0002	USER_REG2
USER_REG3	0x8000.0003	USER_REG3
USER_DBG	0x7510.0000	FMD

## 7.4 Register Map

Table 7-3 on page 273 lists the ROM Controller register and the Flash memory and control registers. The offset listed is a hexadecimal increment to the register's address. The **FMA**, **FMD**, **FMC**, **FCRIS**, **FCIM**, and **FCMISC** register offsets are relative to the Flash memory control base address of 0x400F.D000. The ROM and Flash memory protection register offsets are relative to the System Control base address of 0x400F.E000.

**Table 7-3. Flash Register Map**

Offset	Name	Type	Reset	Description	See page
<b>ROM Registers (System Control Offset)</b>					
0x0F0	RMCTL	R/W1C	-	ROM Control	275

## 7.5 ROM Register Descriptions (System Control Offset)

This section lists and describes the ROM Controller registers, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

## Register 1: ROM Control (RMCTL), offset 0x0F0

This register provides control of the ROM controller state.

### ROM Control (RMCTL)

Base 0x400F.E000

Offset 0x0F0

Type R/W1C, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
reserved																
Type	RO	R/W1C														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	BA	R/W1C	-	<p>Boot Alias</p> <ul style="list-style-type: none"> <li>■ The device has ROM.</li> <li>■ The first two words of the Flash memory contain 0xFFFF.FFFF.</li> </ul> <p>This bit is cleared by writing a 1 to this bit position. When the BA bit is set, the boot alias is in effect and the ROM appears at address 0x0. When the BA bit is clear, the Flash appears at address 0x0.</p>

## 7.6 Flash Register Descriptions (Flash Control Offset)

This section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

## Register 2: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations, this register contains a 1 KB-aligned address and specifies which page is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

### Flash Memory Address (FMA)

Base 0x400F.D000  
Offset 0x000  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16:0	OFFSET	R/W	0x0	Address Offset Address offset in flash where operation is performed, except for nonvolatile registers (see "Nonvolatile Register Programming" on page 272 for details on values for this field).

## Register 3: Flash Memory Data (FMD), offset 0x004

This register contains the data to be written during the programming cycle or read during the read cycle. Note that the contents of this register are undefined for a read access of an execute-only block. This register is not used during the erase cycles.

### Flash Memory Data (FMD)

Base 0x400F.D000  
Offset 0x004  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA	R/W	0x0	Data Value Data value for write operation.

## Register 4: Flash Memory Control (FMC), offset 0x008

When this register is written, the flash controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 276). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 277) is written.

This is the final register written and initiates the memory operation. There are four control bits in the lower byte of this register that, when set, initiate the memory operation. The most used of these register bits are the **ERASE** and **WRITE** bits.

It is a programming error to write multiple control bits and the results of such an operation are unpredictable.

### Flash Memory Control (FMC)

Base 0x400F.D000  
Offset 0x008  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	WRKEY	WO	0x0	Flash Write Key This field contains a write key, which is used to minimize the incidence of accidental flash writes. The value 0xA442 must be written into this field for a write to occur. Writes to the <b>FMC</b> register without this <b>WRKEY</b> value are ignored. A read of this field returns the value 0.
15:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	COMT	R/W	0	Commit Register Value Commit (write) of register value to nonvolatile storage. A write of 0 has no effect on the state of this bit. If read, the state of the previous commit access is provided. If the previous commit access is complete, a 0 is returned; otherwise, if the commit access is not complete, a 1 is returned. This can take up to 50 µs.
2	MERASE	R/W	0	Mass Erase Flash Memory If this bit is set, the flash main memory of the device is all erased. A write of 0 has no effect on the state of this bit. If read, the state of the previous mass erase access is provided. If the previous mass erase access is complete, a 0 is returned; otherwise, if the previous mass erase access is not complete, a 1 is returned. This can take up to 250 ms.

Bit/Field	Name	Type	Reset	Description
1	ERASE	R/W	0	<p>Erase a Page of Flash Memory</p> <p>If this bit is set, the page of flash main memory as specified by the contents of <b>FMA</b> is erased. A write of 0 has no effect on the state of this bit.</p> <p>If read, the state of the previous erase access is provided. If the previous erase access is complete, a 0 is returned; otherwise, if the previous erase access is not complete, a 1 is returned.</p> <p>This can take up to 25 ms.</p>
0	WRITE	R/W	0	<p>Write a Word into Flash Memory</p> <p>If this bit is set, the data stored in <b>FMD</b> is written into the location as specified by the contents of <b>FMA</b>. A write of 0 has no effect on the state of this bit.</p> <p>If read, the state of the previous write update is provided. If the previous write access is complete, a 0 is returned; otherwise, if the write access is not complete, a 1 is returned.</p> <p>This can take up to 50 <math>\mu</math>s.</p>

## Register 5: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C

This register indicates that the flash controller has an interrupt condition. An interrupt is only signaled if the corresponding **FCIM** register bit is set.

### Flash Controller Raw Interrupt Status (FCRIS)

Base 0x400F.D000  
Offset 0x00C  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PRIS	RO	0	<p>Programming Raw Interrupt Status</p> <p>This bit provides status on programming cycles which are write or erase actions generated through the <b>FMC</b> register bits (see page 278).</p> <p>Value Description</p> <ul style="list-style-type: none"> <li>1 The programming cycle has completed.</li> <li>0 The programming cycle has not completed.</li> </ul> <p>This status is sent to the interrupt controller when the <b>PMASK</b> bit in the <b>FCIM</b> register is set.</p> <p>This bit is cleared by writing a 1 to the <b>PMISC</b> bit in the <b>FCMISC</b> register.</p>
0	ARIS	RO	0	<p>Access Raw Interrupt Status</p> <p>Value Description</p> <ul style="list-style-type: none"> <li>1 A program or erase action was attempted on a block of Flash memory that contradicts the protection policy for that block as set in the <b>FMPPEn</b> registers.</li> <li>0 No access has tried to improperly program or erase the Flash memory.</li> </ul> <p>This status is sent to the interrupt controller when the <b>AMASK</b> bit in the <b>FCIM</b> register is set.</p> <p>This bit is cleared by writing a 1 to the <b>AMISC</b> bit in the <b>FCMISC</b> register.</p>

## Register 6: Flash Controller Interrupt Mask (FCIM), offset 0x010

This register controls whether the flash controller generates interrupts to the controller.

### Flash Controller Interrupt Mask (FCIM)

Base 0x400F.D000  
Offset 0x010  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PMASK	R/W	0	<p>Programming Interrupt Mask</p> <p>This bit controls the reporting of the programming raw interrupt status to the interrupt controller.</p> <p>Value Description</p> <ul style="list-style-type: none"> <li>1 An interrupt is sent to the interrupt controller when the PRIS bit is set.</li> <li>0 The PRIS interrupt is suppressed and not sent to the interrupt controller.</li> </ul>
0	AMASK	R/W	0	<p>Access Interrupt Mask</p> <p>This bit controls the reporting of the access raw interrupt status to the interrupt controller.</p> <p>Value Description</p> <ul style="list-style-type: none"> <li>1 An interrupt is sent to the interrupt controller when the ARIS bit is set.</li> <li>0 The ARIS interrupt is suppressed and not sent to the interrupt controller.</li> </ul>

## Register 7: Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014

This register provides two functions. First, it reports the cause of an interrupt by indicating which interrupt source or sources are signalling the interrupt. Second, it serves as the method to clear the interrupt reporting.

### Flash Controller Masked Interrupt Status and Clear (FCMISC)

Base 0x400FD000

Offset 0x014

Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PMISC	R/W1C	0	Programming Masked Interrupt Status and Clear
	Value	Description		
	1	When read, a 1 indicates that an unmasked interrupt was signaled because a programming cycle completed. Writing a 1 to this bit clears PMISC and also the PRIS bit in the <b>FCRIS</b> register (see page 280).		
	0	When read, a 0 indicates that a programming cycle complete interrupt has not occurred. A write of 0 has no effect on the state of this bit.		
0	AMISC	R/W1C	0	Access Masked Interrupt Status and Clear
	Value	Description		
	1	When read, a 1 indicates that an unmasked interrupt was signaled because a program or erase action was attempted on a block of Flash memory that contradicts the protection policy for that block as set in the <b>FMPPEn</b> registers. Writing a 1 to this bit clears AMISC and also the ARIS bit in the <b>FCRIS</b> register (see page 280).		
	0	When read, a 0 indicates that no improper accesses have occurred. A write of 0 has no effect on the state of this bit.		

## 7.7 Flash Register Descriptions (System Control Offset)

The remainder of this section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

## Register 8: USec Reload (USECRL), offset 0x140

**Note:** Offset is relative to System Control base address of 0x400F.E000

This register is provided as a means of creating a 1- $\mu$ s tick divider reload value for the flash controller. The internal flash has specific minimum and maximum requirements on the length of time the high voltage write pulse can be applied. It is required that this register contain the operating frequency (in MHz -1) whenever the flash is being erased or programmed. The user is required to change this value if the clocking conditions are changed for a flash erase/program operation.

### USec Reload (USECRL)

Base 0x400F.E000

Offset 0x140

Type R/W, reset 0x31

## Register 9: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

**Note:** This register is aliased for backwards compatibility.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. For additional information, see the "Flash Memory Protection" section.

### Flash Memory Protection Read Enable 0 (FMPRE0)

Base 0x400F.E000

Offset 0x130 and 0x200

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFFFFFF	Flash Read Enable Configures 2-KB flash blocks to be read only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value      Description 0xFFFFFFFF Bits [31:0] each enable protection on a 2-KB block of Flash memory up to the total of 64 KB.

## Register 10: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

**Note:** This register is aliased for backwards compatibility.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPPEn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. For additional information, see the "Flash Memory Protection" section.

### Flash Memory Protection Program Enable 0 (FMPPE0)

Base 0x400F.E000  
Offset 0x134 and 0x400  
Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	PROG_ENABLE	R/W	0xFFFFFFFF	Flash Programming Enable Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value      Description 0xFFFFFFFF Bits [31:0] each enable protection on a 2-KB block of Flash memory up to the total of 64 KB.

## Register 11: User Debug (USER\_DBG), offset 0x1D0

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register provides a write-once mechanism to disable external debugger access to the device in addition to 27 additional bits of user-defined data. The DBG0 bit (bit 0) is set to 0 from the factory and the DBG1 bit (bit 1) is set to 1, which enables external debuggers. Changing the DBG1 bit to 0 disables any external debugger access to the device permanently, starting with the next power-up cycle of the device. The NW bit (bit 31) indicates that the register has not yet been committed and is controlled through hardware to ensure that the register is only committed once. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. The only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter.

### User Debug (USER\_DBG)

Base 0x400F.E000  
Offset 0x1D0  
Type R/W, reset 0xFFFF.FFFE

Bit/Field	Name	Type	Reset	Description
31	NW	R/W	1	User Debug Not Written When set, this bit indicates that this 32-bit register has not been committed. When clear, this bit specifies that this register has been committed and may not be committed again.
30:2	DATA	R/W	0x1FFFFFF	User Data Contains the user data value. This field is initialized to all 1s and can only be committed once.
1	DBG1	R/W	1	Debug Control 1 The DBG1 bit must be 1 and DBG0 must be 0 for debug to be available.
0	DBG0	R/W	0	Debug Control 0 The DBG1 bit must be 1 and DBG0 must be 0 for debug to be available.

## Register 12: User Register 0 (USER\_REG0), offset 0x1E0

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register provides 31 bits of user-defined data that is non-volatile and can only be written once. Bit 31 indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device.

### User Register 0 (USER\_REG0)

Base 0x400F.E000

30:0	DATA	R/W	0x7FFFFFFF	User Data Contains the user data value. This field is initialized to all 1s and can only be committed once.

## Register 16: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 64 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

### Flash Memory Protection Read Enable 1 (FMPRE1)

Base 0x400F.E000

Offset 0x204

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFFFFFF	Flash Read Enable Configures 2-KB flash blocks to be read only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
				0xFFFFFFFF Bits [31:0] each enable protection on a 2-KB block of Flash memory in memory range from 65 to 128 KB.

## Register 17: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 128 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

31:0                  PROG\_ENABLE                  R/W                  0x00000000          Flash Programming Enable  
Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

#### Value                  Description

0x00000000          Bits [31:0] each enable protection on a 2-KB block of Flash memory in the range from 129 to 192 KB.

## Register 21: Flash Memory Protection Program Enable 3 (FMPPE3), offset 0x40C

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPPEn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 192 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

### Flash Memory Protection Program Enable 3 (FMPPE3)

Base 0x400F.E000  
Offset 0x40C

#### Bit/Field                  Name                  Type                  Reset                  Description

31:0                  PROG\_ENABLE                  R/W                  0x00000000          Flash Programming Enable  
Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

#### Value                  Description

0x00000000          Bits [31:0] each enable protection on a 2-KB block of Flash memory in the range from 193 to 256 KB.

## 8 Micro Direct Memory Access ( $\mu$ DMA)

The LM3S3748 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the expanded available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported peripheral and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller also supports sophisticated transfer modes such as ping-pong and scatter-gather, which allows the processor to set up a list of transfer tasks for the controller.

The  $\mu$ DMA controller has the following features:

- ARM PrimeCell® 32-channel configurable  $\mu$ DMA controller
- Support for multiple transfer modes
  - Basic, for simple transfer scenarios
  - Ping-pong, for continuous data flow to/from peripherals
  - Scatter-gather, from a programmable list of arbitrary transfers initiated from a single request
- Dedicated channels for supported peripherals
- One channel each for receive and transmit path for bidirectional peripherals
- Dedicated channel for software-initiated transfers
- Independently configured and operated channels
- Per-channel configurable bus arbitration scheme
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable device requests
- Optional software initiated requests for any channel
- Interrupt on transfer completion, with a separate interrupt per channel

## 8.1 Block Diagram

Figure 8-1. μDMA Block Diagram

## 8.2 Functional Description

The μDMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M3 processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The DMA controller's usage of the bus is always subordinate to the processor core, and so it will never hold up a bus transaction by the processor. Because the μDMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly reduce contention between the processor core and the μDMA controller, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allows both the processor core and the μDMA controller to access the bus and perform simultaneous data transfers.

Each peripheral function that is supported has a dedicated channel on the μDMA controller that can be configured independently.

The μDMA controller makes use of a unique configuration method by using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that will be transferred in a burst before the controller re-arbitrates for channel priority. Using the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a DMA service request.

### 8.2.1 Channel Assignments

$\mu$ DMA channels 0-31 are assigned to peripherals according to the following table.

**Note:** Channels that are not listed in the table may be assigned to peripherals in the future. However, they are currently available for software use.

**Table 8-1. DMA Channel Assignments**

DMA Channel	Peripheral Assigned
0	USB Endpoint 1 Receive
1	USB Endpoint 1 Transmit
2	USB Endpoint 2 Receive
3	USB Endpoint 2 Transmit
4	USB Endpoint 3 Receive
5	USB Endpoint 3 Transmit
8	UART0 Receive
9	UART0 Transmit
10	SSI0 Receive
11	SSI0 Transmit
22	UART1 Receive
23	UART1 Transmit
24	SSI1 Receive
25	SSI1 Transmit
30	Dedicated for software use

### 8.2.2 Priority

The  $\mu$ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSSET)** register, and cleared with the **DMA Channel Priority Clear (DMAPRIOCCLR)** register.

### 8.2.3 Arbitration Size

When a  $\mu$ DMA channel requests a transfer, the  $\mu$ DMA controller arbitrates between all the channels making a request and services the DMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before rearbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the  $\mu$ DMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority DMA channel uses a large arbitration size, the latency for higher priority channels will be increased because the  $\mu$ DMA controller will complete the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that will be transferred at any one time in a burst. Here, the term arbitration refers to determination of DMA channel priority, not arbitration for the bus. When the µDMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the µDMA controller will be held off whenever the processor needs to perform a bus transaction on the same bus, even in the middle of a burst transfer.

### 8.2.4 Request Types

The µDMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The µDMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted and the µDMA channel has been set up for a burst transfer, then the burst request takes precedence. See Table 8-2 on page 301, which shows how each peripheral supports the two request types.

**Table 8-2. Request Type Support**

Peripheral	Single Request Signal	Burst Request Signal
USB TX	None	FIFO TXRDY
USB RX	None	FIFO RXRDY
UART TX	TX FIFO Not Full	TX FIFO Level (configurable)
UART RX	RX FIFO Not Empty	RX FIFO Level (configurable)
SSI TX	TX FIFO Not Full	TX FIFO Level (fixed at 4)
SSI RX	RX FIFO Not Empty	RX FIFO Level (fixed at 4)

#### 8.2.4.1 Single Request

When a single request is detected, and not a burst request, the µDMA controller will transfer one item, and then stop and wait for another request.

#### 8.2.4.2 Burst Request

When a burst request is detected, the µDMA controller will transfer the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART will generate a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the µDMA controller will only respond to burst requests for that channel.

### 8.2.5 Channel Configuration

The µDMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 8-3 on page 302 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table needs to be allocated in memory. The second half of the control table is not needed and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

**Table 8-3. Control Structure Memory Map**

Offset	Channel
0x0	0, Primary
0x10	1, Primary
...	...
0x1F0	31, Primary
0x200	0, Alternate
0x210	1, Alternate
...	...
0x3F0	31, Alternate

Table 8-4 on page 302 shows an individual control structure entry in the control table. Each entry has a source and destination *end* pointer. These pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

**Table 8-4. Channel Control Structure**

Offset	Description
0x000	Source End Pointer
0x004	Destination End Pointer
0x008	Control Word
0x00C	Unused

The remaining part of the control structure is the control word. The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag

- Transfer mode

The control word and each field are described in detail in “ $\mu$ DMA Channel Control Structure” on page 319. The  $\mu$ DMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size will indicate 0, and the transfer mode will indicate “stopped”. Since the control word is modified by the  $\mu$ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a  $\mu$ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set ((DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete DMA transfer, the controller will automatically disable the channel.

## 8.2.6 Transfer Modes

The  $\mu$ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. There are several complex modes that are meant to support a continuous flow of data.

### 8.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the  $\mu$ DMA controller will not perform a transfer and will disable the channel if it is enabled. At the end of a transfer, the  $\mu$ DMA controller will update the control word to set the mode to Stop.

### 8.2.6.2 Basic Mode

In Basic mode, the  $\mu$ DMA controller will perform transfers as long as there are more items to transfer and a transfer request is present. This mode is used with peripherals that assert a DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary but the entire transfer should be completed. For example, for a software initiated transfer, the request is momentary, and if Basic mode is used then only one item will be transferred on a software request.

When all of the items have been transferred using Basic mode, the  $\mu$ DMA controller will set the mode for that channel to Stop.

### 8.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received the transfer will run to completion, even if the DMA request is removed. This mode is suitable for software-triggered transfers. Generally, you would not use Auto mode with a peripheral.

When all the items have been transferred using Auto mode, the  $\mu$ DMA controller will set the mode for that channel to Stop.

### 8.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures are used. Both are set up by the processor for data transfer between memory and a peripheral. Then the transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the  $\mu$ DMA controller will then read the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and

alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 8-2 on page 304 for an example showing operation in Ping-Pong mode.

**Figure 8-2. Example of Ping-Pong DMA Transaction**

### 8.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data needs to be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather DMA operation could be used to selectively read the payload of several stored packets of a communication protocol, and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The μDMA controller alternates between using the primary control structure to copy the next transfer instruction from the list, and then executing the new transfer instruction. The end of the list is marked by setting the control word for the last entry to use Basic transfer mode. Once the last transfer is performed using Basic mode, the μDMA controller will stop. A completion interrupt will only be generated after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly by programming a write to the software trigger for another channel, or indirectly by causing a peripheral action that will result in a μDMA request.

By programming the μDMA controller using this method, a set of arbitrary transfers can be performed based on a single DMA request.

Refer to Figure 8-3 on page 306 and Figure 8-4 on page 307, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory will be copied together into one buffer. Figure 8-3 on page 306 shows how the application sets up a μDMA *task list* in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that will be used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-4 on page 307 shows the sequence as the μDMA controller performs the three sets of copy operations. First, using the primary control structure, the μDMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the μDMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

**Figure 8-3. Memory Scatter-Gather, Setup and Configuration**

**Figure 8-4. Memory Scatter-Gather, μDMA Copy Sequence**

Using the channel's primary control structure, the μDMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μDMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the μDMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μDMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the μDMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μDMA controller copies data from the source buffer C to the destination buffer.

### 8.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a DMA request. Upon detecting a DMA request from the peripheral, the  $\mu$ DMA controller will use the primary control structure to copy one entry from the list to the alternate control structure, and then perform the transfer. At the end of this transfer, the next transfer will only be started if the peripheral again asserts a DMA request. The  $\mu$ DMA controller will continue to perform transfers from the list only when the peripheral is making a request, until the last transfer is complete. A completion interrupt will only be generated after the last transfer.

By programming the  $\mu$ DMA controller using this method, data can be transferred to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 8-5 on page 309 and Figure 8-6 on page 310, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory will be copied to a single peripheral data register. Figure 8-5 on page 309 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that will be used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-6 on page 310 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

**Figure 8-5. Peripheral Scatter-Gather, Setup and Configuration****NOTES:**

1. Application has a need to copy data items from three separate location in memory into a peripheral data register.
2. Application sets up μDMA “task list” in memory, which contains the pointers and control configuration for three uDMA copy “tasks.”
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it will be executed by the μDMA controller.

**Figure 8-6. Peripheral Scatter-Gather,  $\mu$ DMA Copy Sequence**

### 8.2.7 Transfer Size and Increment

The μDMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 8-5 on page 311 shows the configuration to read from a peripheral that supplies 8-bit data.

**Table 8-5. μDMA Read Example: 8-Bit Peripheral**

Field	Configuration
Source data size	8 bits
Destination data size	8 bits
Source address increment	No increment
Destination address increment	Byte
Source end pointer	Peripheral read FIFO register
Destination end pointer	End of the data buffer in memory

### 8.2.8 Peripheral Interface

Each peripheral that supports μDMA has a DMA single request and/or burst request signal that is asserted when the device is ready to transfer data. The request signal can be disabled or enabled by using the **DMA Channel Request Mask Set (DMAREQMASKSET)** and **DMA Channel Request Mask Clear (DMAREQMASKCLR)** registers. The DMA request signal is disabled, or masked, when the channel request mask bit is set. When the request is not masked, the DMA channel is configured correctly and enabled, and the peripheral asserts the DMA request signal, the μDMA controller will begin the transfer.

When a DMA transfer is complete, the μDMA controller asserts a DMA Done signal, which is routed through the interrupt vector of the peripheral. Therefore, if DMA is used to transfer data for a peripheral and interrupts are used, then the interrupt handler for that peripheral must be designed to handle the μDMA transfer completion interrupt. When DMA is enabled for a peripheral, the μDMA controller will mask the normal interrupts for a peripheral. This means that when a large amount of data is transferred using DMA, instead of receiving multiple interrupts from the peripheral as data flows, the processor will only receive one interrupt when the transfer is complete.

The interrupt request from the μDMA controller is automatically cleared when the interrupt handler is activated.

### 8.2.9 Software Request

There is a dedicated μDMA channel for software-initiated transfers. This channel also has a dedicated interrupt to signal completion of a DMA transfer. A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral DMA channel, then the completion interrupt will occur on the interrupt vector for the peripheral instead of the software interrupt vector. This means that any

channel may be used for software requests as long as the corresponding peripheral is not using  $\mu$ DMA.

### 8.2.10 Interrupts and Errors

When a DMA transfer is complete, the  $\mu$ DMA controller will generate a completion interrupt on the interrupt vector of the peripheral. If the transfer uses the software DMA channel, then the completion interrupt will occur on the dedicated software DMA interrupt vector.

If the  $\mu$ DMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it will disable the DMA channel that caused the error, and generate an interrupt on the  $\mu$ DMA Error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The `ERRCLR` bit will be set if an error occurred. The error can be cleared by writing a 1 to the `ERRCLR` bit.

If the peripheral generates an error that causes an interrupt, the interrupt will be generated on the interrupt vector for that peripheral. This is the same whether or not  $\mu$ DMA is being used with the peripheral.

Table 8-6 on page 312 shows the dedicated interrupt assignments for the  $\mu$ DMA controller.

**Table 8-6.  $\mu$ DMA Interrupt Assignments**

Interrupt	Assignment
46	$\mu$ DMA Software Channel Transfer
47	$\mu$ DMA Error

## 8.3 Initialization and Configuration

### 8.3.1 Module Initialization

Before the  $\mu$ DMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. The  $\mu$ DMA peripheral must be enabled in the System Control block. To do this, set the `UDMA` bit of the System Control **RCGC2** register.
2. Enable the  $\mu$ DMA controller by setting the `MASTEREN` bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

### 8.3.2 Configuring a Memory-to-Memory Transfer

$\mu$ DMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

#### 8.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Set bit 30 of the **DMA Channel Priority Set (DMAPIOSET)** or **DMA Channel Priority Clear (DMAPIOCLR)** registers to set the channel to High priority or Default priority.

2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μDMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μDMA controller to recognize requests for this channel.

### 8.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example will transfer 256 32-bit words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 8-7 on page 313.

**Table 8-7. Channel Control Structure Offsets for Channel 30**

Offset	Description
Control Table Base + 0x1E0	Channel 30 Source End Pointer
Control Table Base + 0x1E4	Channel 30 Destination End Pointer
Control Table Base + 0x1E8	Channel 30 Control Word

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Set the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Set the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 8-8 on page 313.

**Table 8-8. Channel Control Word Configuration for Memory Transfer Example**

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	2	32-bit destination address increment
DSTSIZE	29:28	2	32-bit destination data size
SRCINC	27:26	2	32-bit source address increment
SRCSIZE	25:24	2	32-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	255	Transfer 256 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	2	Use Auto-request transfer mode

### 8.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.

2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The DMA transfer will now take place. If the interrupt is enabled, then the processor will be notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit will be automatically cleared when the transfer is complete. The status can also be checked by reading the **XFERMODE** field of the channel control word at offset 0x1E8. This field will automatically be set to 0 at the end of the transfer.

### 8.3.3 Configuring a Peripheral for Simple Transmit

This example will set up the  $\mu$ DMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral will use  $\mu$ DMA channel 7.

#### 8.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Set bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

#### 8.3.3.2 Configure the Channel Control Structure

Now the channel control structure must be configured. This example will transfer 64 8-bit bytes from a memory buffer to the peripheral's transmit FIFO register. This example uses  $\mu$ DMA channel 7, and the control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 8-9 on page 314.

**Table 8-9. Channel Control Structure Offsets for Channel 7**

Offset	Description
Control Table Base + 0x070	Channel 7 Source End Pointer
Control Table Base + 0x074	Channel 7 Destination End Pointer
Control Table Base + 0x078	Channel 7 Control Word

#### Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Since the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Set the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Set the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 8-10 on page 315.

**Table 8-10. Channel Control Word Configuration for Peripheral Transmit Example**

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	3	Destination address does not increment
DSTSIZEx	29:28	0	8-bit destination data size
SRCINC	27:26	0	8-bit source address increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	2	Arbitrates after 4 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	1	Use Basic transfer mode

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Since the peripheral has a FIFO that will trigger at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes will be transferred, which is what the FIFO can accomodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte will be transferred at a time. If it is important to the application that transfers only be made in bursts, then the channel useburst SET[n] bit should be set by writing a 1 to bit 7 of the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

### 8.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The µDMA controller is now configured for transfer on channel 7. The controller will make transfers to the peripheral whenever the peripheral asserts a DMA request. The transfers will continue until the entire buffer of 64 bytes has been transferred. When that happens, the µDMA controller will disable the channel and set the XFERMODE field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit will be automatically cleared when the transfer is complete. The status can also be checked by reading the XFERMODE field of the channel control word at offset 0x078. This field will automatically be set to 0 at the end of the transfer.

If peripheral interrupts were enabled, then the peripheral interrupt handler would receive an interrupt when the entire transfer was complete.

### 8.3.4 Configuring a Peripheral for Ping-Pong Receive

This example will set up the µDMA controller to continuously receive 8-bit data from a peripheral into a pair of 64 byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral will use µDMA channel 8.

#### 8.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Set bit 8 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.

2. Set bit 8 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 8 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 8 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

#### 8.3.4.2 Configure the Channel Control Structure

Now the channel control structure must be configured. This example will transfer 8-bit bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the  $\mu$ DMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 8-11 on page 316.

**Table 8-11. Primary and Alternate Channel Control Structure Offsets for Channel 8**

Offset	Description
Control Table Base + 0x080	Channel 8 Primary Source End Pointer
Control Table Base + 0x084	Channel 8 Primary Destination End Pointer
Control Table Base + 0x088	Channel 8 Primary Control Word
Control Table Base + 0x280	Channel 8 Alternate Source End Pointer
Control Table Base + 0x284	Channel 8 Alternate Destination End Pointer
Control Table Base + 0x288	Channel 8 Alternate Control Word

#### Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Since the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Set the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.
2. Set the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Set the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Set the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088, and the alternate control word at offset 0x288 must be programmed according to Table 8-10 on page 315. Both control words are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 8-12 on page 317.
2. Program the alternate channel control word at offset 0x288 according to Table 8-12 on page 317.

**Table 8-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example**

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	0	8-bit destination address increment
DSTSIZEx	29:28	0	8-bit destination data size
SRCINC	27:26	3	Source address does not increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	3	Use Ping-Pong transfer mode

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Since the peripheral has a FIFO that will trigger at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes will be transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte will be transferred at a time. If it is important to the application that transfers only be made in bursts, then the channel useburst SET[n] bit should be set by writing a 1 to bit 8 of the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

#### 8.3.4.3 Configure the Peripheral Interrupt

In order to use µDMA Ping-Pong mode, it is best to use an interrupt handler. (It is also possible to use ping-pong mode without interrupts by polling). The interrupt handler will be triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

#### 8.3.4.4 Enable the µDMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

#### 8.3.4.5 Process Interrupts

The µDMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the DMA request signal, the µDMA controller will make transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it will switch to the alternate channel control structure and make transfers into buffer B. At the same time, the primary channel control word mode field will be set to indicate Stopped, and an interrupt will be triggered.

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data, or set a flag that the data needs to be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the XFERMODE field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:

- a. Process the newly received data in buffer A, or signal the buffer processing code that buffer A has data available.
  - b. Reprogram the primary channel control word at offset 0x88 according to Table 8-12 on page 317.
2. Read the alternate channel control word at offset 0x288 and check the XFERMODE field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
- a. Process the newly received data in buffer B, or signal the buffer processing code that buffer B has data available.
  - b. Reprogram the alternate channel control word at offset 0x288 according to Table 8-12 on page 317.

## 8.4 Register Map

Table 8-13 on page 318 lists the  $\mu$ DMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, that is, the base address is n/a (not applicable). In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See “Channel Configuration” on page 301 and Table 8-3 on page 302 for a description of how the entries in the channel control table are located in memory. The  $\mu$ DMA register addresses are given as a hexadecimal increment, relative to the  $\mu$ DMA base address of 0x400F.F000. Note that the  $\mu$ DMA module clock must be enabled before the registers can be programmed (see page 237). There must be a delay of 3 system clocks after the  $\mu$ DMA module clock is enabled before any  $\mu$ DMA module registers are accessed.

**Table 8-13.  $\mu$ DMA Register Map**

## 8.5 μDMA Channel Control Structure

The μDMA Channel Control Structure holds the DMA transfer settings for a DMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 301 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. There is a primary and alternate structure for each channel. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

## Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000

**DMA Channel Source Address End Pointer (DMASRCENDP)** is part of the Channel Control Structure, and is used to specify the source address for a DMA transfer.

### DMA Channel Source Address End Pointer (DMASRCENDP)

Base n/a  
Offset 0x000  
Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Source Address End Pointer Points to the last address of the DMA transfer source (inclusive). If the source address is not incrementing, then this points at the source location itself (such as a peripheral data register).

## Register 2: DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004

**DMA Channel Destination Address End Pointer (DMADSTENDP)** is part of the Channel Control Structure, and is used to specify the destination address for a DMA transfer.

### DMA Channel Destination Address End Pointer (DMADSTENDP)

Base n/a  
Offset 0x004  
Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Destination Address End Pointer Points to the last address of the DMA transfer destination (inclusive). If the destination address is not incrementing, then this points at the destination location itself (such as a peripheral data register).

### Register 3: DMA Channel Control Word (DMACHCTL), offset 0x008

**DMA Channel Control Word (DMACHCTL)** is part of the Channel Control Structure, and is used to specify parameters of a DMA transfer.

#### DMA Channel Control Word (DMACHCTL)

Base n/a  
Offset 0x008  
Type R/W, reset -

23:18	reserved	R/W	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										

Bit/Field	Name	Type	Reset	Description																								
17:14	ARBSIZE	R/W	-	<p>Arbitration Size Sets the number of DMA transfers that can occur before the controller re-arbitrates. The possible arbitration rate settings represent powers of 2 and are shown below.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>1 Transfer Arbitrates after each DMA transfer.</td></tr> <tr> <td>0x1</td><td>2 Transfers</td></tr> <tr> <td>0x2</td><td>4 Transfers</td></tr> <tr> <td>0x3</td><td>8 Transfers</td></tr> <tr> <td>0x4</td><td>16 Transfers</td></tr> <tr> <td>0x5</td><td>32 Transfers</td></tr> <tr> <td>0x6</td><td>64 Transfers</td></tr> <tr> <td>0x7</td><td>128 Transfers</td></tr> <tr> <td>0x8</td><td>256 Transfers</td></tr> <tr> <td>0x9</td><td>512 Transfers</td></tr> <tr> <td>0xA-0xF</td><td>1024 Transfers This means that no arbitration occurs during the DMA transfer because the maximum transfer size is 1024.</td></tr> </tbody> </table>	Value	Description	0x0	1 Transfer Arbitrates after each DMA transfer.	0x1	2 Transfers	0x2	4 Transfers	0x3	8 Transfers	0x4	16 Transfers	0x5	32 Transfers	0x6	64 Transfers	0x7	128 Transfers	0x8	256 Transfers	0x9	512 Transfers	0xA-0xF	1024 Transfers This means that no arbitration occurs during the DMA transfer because the maximum transfer size is 1024.
Value	Description																											
0x0	1 Transfer Arbitrates after each DMA transfer.																											
0x1	2 Transfers																											
0x2	4 Transfers																											
0x3	8 Transfers																											
0x4	16 Transfers																											
0x5	32 Transfers																											
0x6	64 Transfers																											
0x7	128 Transfers																											
0x8	256 Transfers																											
0x9	512 Transfers																											
0xA-0xF	1024 Transfers This means that no arbitration occurs during the DMA transfer because the maximum transfer size is 1024.																											
13:4	XFERSIZE	R/W	-	<p>Transfer Size (minus 1) Sets the total number of items to transfer. The value of this field is 1 less than the number to transfer (value 0 means transfer 1 item). The maximum value for this 10-bit field is 1023 which represents a transfer size of 1024 items. The transfer size is the number of items, not the number of bytes. If the data size is 32 bits, then this value is the number of 32-bit words to transfer. The controller updates this field immediately prior to it entering the arbitration process, so it contains the number of outstanding DMA items that are necessary to complete the DMA cycle.</p>																								
3	NXTUSEBURST	R/W	-	<p>Next Useburst Controls whether the useburst <math>SET[n]</math> bit is automatically set for the last transfer of a peripheral scatter-gather operation. Normally, for the last transfer, if the number of remaining items to transfer is less than the arbitration size, the controller will use single transfers to complete the transaction. If this bit is set, then the controller will only use a burst transfer to complete the last transfer.</p>																								

Bit/Field	Name	Type	Reset	Description
2:0	XFERMODE	R/W	-	DMA Transfer Mode Since this register is in system RAM, it has no reset value. Therefore, this field should be initialized to 0 before the channel is enabled. The operating mode of the DMA cycle. Refer to “Transfer Modes” on page 303 for a detailed explanation of transfer modes.
Value Description				
0x0 Stop Channel is stopped, or configuration data is invalid.				
0x1 Basic The controller must receive a new request, prior to it entering the arbitration process, to enable the DMA cycle to complete.				
0x2 Auto-Request The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of Xfersize items without any further requests.				
0x3 Ping-Pong The controller performs a DMA cycle using one of the channel control structures. After the DMA cycle completes, it performs a DMA cycle using the other channel control structure. After the next DMA cycle completes (and provided that the host processor has updated the original channel control data structure), it performs a DMA cycle using the original channel control data structure. The controller continues to perform DMA cycles until it either reads an invalid data structure or the host processor changes this field to 0x1 or 0x2. See “Ping-Pong” on page 303.				
0x4 Memory Scatter-Gather When the controller operates in Memory Scatter-Gather mode, you must only use this value in the primary channel control data structure. See “Memory Scatter-Gather” on page 305.				
0x5 Alternate Memory Scatter-Gather When the controller operates in Memory Scatter-Gather mode, you must only use this value in the alternate channel control data structure.				
0x6 Peripheral Scatter-Gather When the controller operates in Peripheral Scatter-Gather mode, you must only use this value in the primary channel control data structure. See “Peripheral Scatter-Gather” on page 308.				
0x7 Alternate Peripheral Scatter-Gather When the controller operates in Peripheral Scatter-Gather mode, you must only use this value in the alternate channel control data structure.				

## 8.6 μDMA Register Descriptions

The register addresses given are relative to the μDMA base address of 0x400F.F000.

**Register 4: DMA Status (DMASTAT), offset 0x000**

The **DMA Status (DMASTAT)** register returns the status of the controller. You cannot read this register when the controller is in the reset state.

**DMA Status (DMASTAT)**

Base 0x400F.F000  
Offset 0x000  
Type RO, reset 0x001F.0000

Bit/Field	Name	Type	Reset	Description
31:21	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20:16	DMACHANS	RO	0x1F	Available DMA Channels Minus 1 This bit contains a value equal to the number of DMA channels the controller is configured to use, minus one. That is, 32 DMA channels.
15:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 5: DMA Configuration (DMACFG), offset 0x004**

The **DMACFG** register controls the configuration of the controller.

## DMA Configuration (DMACFG)

Base 0x400F.F000  
Offset 0x004  
Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:1	reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MASTEN	WO	-	Controller Master Enable Enables the controller.
Value Description				
0      Disables				
1      Enables				

## Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that you must assign to the controller depends on the number of DMA channels used and whether you configure it to use the alternate channel control data structure. See “Channel Configuration” on page 301 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. You cannot read this register when the controller is in the reset state.

### DMA Channel Control Base Pointer (DMACTLBASE)

Base 0x400F.F000  
Offset 0x008  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	ADDR	R/W	0x00	Channel Control Base Address Pointer to the base address of the channel control table. The base address must be 1024-byte aligned.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. You cannot read this register when the controller is in the reset state.

### DMA Alternate Channel Control Base Pointer (DMAALTBASE)

Base 0x400F.F000

Offset 0x00C

Type RO, reset 0x0000.0200

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RO	0x200	Alternate Channel Address Pointer Provides the base address of the alternate channel control structures.

## Register 8: DMA Channel Wait on Request Status (DMAWAITSTAT), offset 0x010

This read-only register indicates that the µDMA channel is waiting on a request. A peripheral can pull this Low to hold off the µDMA from performing a single request until the peripheral is ready for a burst request. The use of this feature is dependent on the design of the peripheral and is used to enhance performance of the µDMA with that peripheral. You cannot read this register when the controller is in the reset state.

DMA Channel Wait on Request Status (DMAWAITSTAT)

Base 0x400F.F000

Offset 0x010

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	WAITREQ[n]	RO	0x00	Channel [n] Wait Status Channel wait on request status. For each channel 0 through 31, a 1 in the corresponding bit field indicates that the channel is waiting on a request.

**Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014**

Each bit of the **DMASWREQ** register represents the corresponding DMA channel. When you set a bit, it generates a request for the specified DMA channel.

## DMA Channel Software Request (DMASWREQ)

Base 0x400F.F000

Offset 0x014

Type WO, reset -

## Bit/Field      Name      Type      Reset      Description

31:0	<b>SWREQ[n]</b>	WO	-	Channel [n] Software Request For each channel 0 through 31, write a 1 to the corresponding bit field to generate a software DMA request for that DMA channel. Writing a 0 does not create a DMA request for the corresponding channel.
------	-----------------	----	---	---

## Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018

Each bit of the **DMAUSEBURSTSET** register represents the corresponding DMA channel. Writing a 1 disables the peripheral's single request input from generating requests, and therefore only the peripheral's burst request generates requests. Reading the register returns the status of useburst.

When there are fewer items remaining to transfer than the arbitration (burst) size, the controller automatically clears the useburst bit to 0. This enables the remaining items to transfer using single requests. This bit should not be set for a peripheral's channel that does not support the burst request model.

Refer to “Request Types” on page 301 for more details about request types.

Value Description				
0	No Effect			Use the <b>DMAUSEBURSTCLR</b> register to clear bit [n] to 0.
1	Burst Only			DMA channel [n] responds only to burst requests.

## Register 11: DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C

Each bit of the **DMAUSEBURSTCLR** register represents the corresponding DMA channel. Writing a 1 enables `dma_sreq[n]` to generate requests.

### DMA Channel Useburst Clear (DMAUSEBURSTCLR)

Base 0x400F.F000

Offset 0x01C

Type WO, reset -

Bit/Field      Name      Type      Reset      Description

31:0      CLR[n]      WO      -      Channel [n] Useburst Clear  
Clears useburst bit on channel [n].

Value      Description

0      No Effect  
Use the **DMAUSEBURSTSET** to set bit [n] to 1.

1      Single and Burst  
DMA channel [n] responds to single and burst requests.

## Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding DMA channel. Writing a 1 disables DMA requests for the channel. Reading the register returns the request mask status. When a  $\mu$ DMA channel's request is masked, that means the peripheral can no longer request  $\mu$ DMA transfers. The channel can then be used for software-initiated transfers.

### Reads

31:0                  SET[n]                  R                  0x00                  Channel [n] Priority Status  
Returns the channel priority status.

Value	Description
0	Default Priority DMA channel [n] is using the default priority level.
1	High Priority DMA channel [n] is using a High Priority level.

### Writes

#### DMA Channel Priority Set (DMAPRIOSSET)

Base 0x400F.F000  
Offset 0x038  
Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	W	0x00	Channel [n] Priority Set Sets the channel priority to high.
Value Description				
0	No Effect			Use the <b>DMAPRIOCLR</b> register to set channel [n] to the default priority level.
1	High Priority			Sets DMA channel [n] to a High Priority level.

## Register 19: DMA Channel Priority Clear (DMAPRIOCLR), offset 0x03C

Each bit of the **DMAPRIOCLR** register represents the corresponding DMA channel. Writing a 1 configures the DMA channel to have the default priority level.

### DMA Channel Priority Clear (DMAPRIOCLR)

Base 0x400F.F000

Offset 0x03C

Type WO, reset -

Bit/Field      Name      Type      Reset      Description

31:0      CLR[n]      WO      -      Channel [n] Priority Clear  
Set the appropriate bit to clear the high priority level for the specified DMA channel.

Value	Description
0	No Effect Use the <b>DMAPRIOSET</b> register to set channel [n] to the High priority level.
1	Default Priority Sets DMA channel [n] to a Default priority level.

## Register 20: DMA Bus Error Clear (DMAERRCLR), offset 0x04C

The **DMAERRCLR** register is used to read and clear the DMA bus error status. The error status will be set if the  $\mu$ DMA controller encountered a bus error while performing a DMA transfer. If a bus error occurs on a channel, that channel will be automatically disabled by the  $\mu$ DMA controller. The other channels are unaffected.

**Register 25: DMA Peripheral Identification 4 (DMAPeriphID4), offset 0xFD0**

The **DMAPeriphIDn** registers are hard-coded and the fields within the registers determine the reset values.

## DMA Peripheral Identification 4 (DMAPeriphID4)

Base 0x400F.F000  
Offset 0xFD0  
Type RO, reset 0x0000.0004

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID4	RO	0x04	DMA Peripheral ID Register Can be used by software to identify the presence of this peripheral.

## Register 26: DMA PrimeCell Identification 0 (DMA\_PCellID0), offset 0xFF0

The **DMAPCellIDn** registers are hard-coded and the fields within the registers determine the reset values.

DMA PrimeCell Identification 0 (DMA\_PCellID0)

Base 0x400F.F000  
Offset 0xFF0  
Type RO, reset 0x0000.000D

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID0	RO	0x0D	DMA PrimeCell ID Register[7:0] Provides software a standard cross-peripheral identification system.

## Register 27: DMA PrimeCell Identification 1 (DMAPCellID1), offset 0xFF4

The **DMAPCellIDn** registers are hard-coded and the fields within the registers determine the reset values.

### DMA PrimeCell Identification 1 (DMAPCellID1)

Base 0x400F.F000  
Offset 0xFF4  
Type RO, reset 0x0000.00F0

## Register 28: DMA PrimeCell Identification 2 (DMAPCellID2), offset 0xFF8

The **DMAPCellIDn** registers are hard-coded and the fields within the registers determine the reset values.

### DMA PrimeCell Identification 2 (DMAPCellID2)

Base 0x400F.F000  
Offset 0xFF8  
Type RO, reset 0x0000.0005

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID2	RO	0x05	DMA PrimeCell ID Register[23:16] Provides software a standard cross-peripheral identification system.

**Register 29: DMA PrimeCell Identification 3 (DMAPCellID3), offset 0xFFC**

The **DMAPCellIDn** registers are hard-coded and the fields within the registers determine the reset values.

## DMA PrimeCell Identification 3 (DMAPCellID3)

Base 0x400F.F000  
Offset 0xFFC  
Type RO, reset 0x0000.00B1

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID3	RO	0xB1	DMA PrimeCell ID Register[31:24] Provides software a standard cross-peripheral identification system.

## 9 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of eight physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F, Port G, Port H). The GPIO module supports 3-61 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- 3-61 GPIOs, depending on configuration
- 5-V-tolerant in input configuration
- Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can initiate an ADC sample sequence
- Pins configured as digital inputs are Schmitt-triggered.
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
  - Slew rate control for the 8-mA drive
  - Open drain enables
  - Digital input enables

### 9.1 Functional Description

**Important:** All GPIO pins are tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**), with the exception of the four JTAG/SWD pins ( $PC[3:0]$ ). The JTAG/SWD pins default to their JTAG/SWD functionality (**GPIOAFSEL=1**, **GPIODEN=1** and **GPIOPUR=1**). A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts both groups of pins back to their default state.

Each GPIO port is a separate hardware instantiation of the same physical block(see Figure 9-1 on page 360 and Figure 9-2 on page 361). The LM3S3748 microcontroller contains eight ports and thus eight of these physical GPIO blocks.

**Figure 9-1. Digital I/O Pads**

**Figure 9-2. Analog/Digital I/O Pads**

## 9.1.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

### 9.1.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 369) is used to configure each individual pin as an input or output. When the data direction bit is set to 0, the GPIO is configured as an input and the corresponding data register bit will capture and store the value on the GPIO port. When the data direction bit is set to 1, the GPIO is configured as an output and the corresponding data register bit will be driven out on the GPIO port.

### 9.1.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 368) by using bits [9:2] of the address bus as a mask. This allows software drivers to modify individual GPIO pins in a single instruction, without affecting the state of the other pins. This is in contrast to the "typical" method of doing a read-modify-write

operation to set or clear an individual GPIO pin. To accommodate this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set to 1, the value of the **GPIODATA** register is altered. If it is cleared to 0, it is left unchanged.

For example, writing a value of 0xEB to the address **GPIODATA** + 0x098 would yield as shown in Figure 9-3 on page 362, where *u* is data unchanged by the write.

**Figure 9-3. GPIODATA Write Example**

During a read, if the address bit associated with the data bit is set to 1, the value is read. If the address bit associated with the data bit is set to 0, it is read as a zero, regardless of its actual value. For example, reading address **GPIODATA** + 0x0C4 yields as shown in Figure 9-4 on page 362.

**Figure 9-4. GPIODATA Read Example**

## 9.1.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. With these registers, it is possible to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, it is assumed that the external source holds the level constant for the interrupt to be recognized by the controller.

Three registers are required to define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 370)
- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 371)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 372)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 373).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOIMIS)** registers (see page 374 and page 375). As the name implies, the **GPIOIMIS** register only shows interrupt conditions that are allowed to be passed to the controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the controller.

In addition to providing GPIO functionality, PB4 can also be used as an external trigger for the ADC. If PB4 is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set to 1), not only is an interrupt for PortB generated, but an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated.

If no other PortB pins are being used to generate interrupts, the **Interrupt 0-31 Set Enable (EN0)** register can disable the PortB interrupts, and the ADC interrupt can be used to read back the converted data. Otherwise, the PortB interrupt handler needs to ignore and clear interrupts on PB4, and wait for the ADC interrupt or the ADC interrupt must be disabled in the **EN0** register and the PortB interrupt handler must poll the ADC registers until the conversion is completed. See page 112 for more information.

Interrupts are cleared by writing a 1 to the appropriate bit of the **GPIO Interrupt Clear (GPIOICR)** register (see page 377).

When programming the following interrupt control registers, the interrupts should be masked (**GPIOIM** set to 0). Writing any value to an interrupt control register (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**) can generate a spurious interrupt if the corresponding bits are enabled.

### 9.1.3 Mode Control

The GPIO pins can be controlled by either hardware or software. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 378), the pin state is controlled by its alternate function (that is, the peripheral). Software control corresponds to GPIO mode, where the **GPIODATA** register is used to read/write the corresponding pins.

**Note:** If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be written to 1 to disable the analog isolation circuit.

### 9.1.4 Commit Control

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin (PB7) and the four JTAG/SWD pins (**PC[3:0]**). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 378), **GPIO Pull-Up Select (GPIOPUR)** register (see page 384), and **GPIO Digital Enable (GPIODEN)** register (see page 388) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 390) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 391) have been set to 1.

### 9.1.5 Pad Control

The pad control registers allow for GPIO pad configuration by software based on the application requirements. The pad control registers include the **GPIOODR2R**, **GPIOODR4R**, **GPIOODR8R**, **GPIOODR**, **GPIOPUR**, **GPIOPDR**, **GPIOSLR**, and **GPIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable.

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the  $V_{OL}$  value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only

a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

### 9.1.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GPIOPeriphID7** registers as well as the **GPIOCellIID0-GPIOCellIID3** registers.

## 9.2 Initialization and Configuration

The GPIO modules may be accessed via two different memory apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris® parts. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus. These apertures are mutually exclusive. The aperture enabled for a given GPIO port is controlled by the appropriate bit in the **GPIOHBCTL** register (see page 201).

To use the GPIO, the peripheral clock must be enabled by setting the appropriate GPIO Port bit field (**GPIOOn**) in the **RCGC2** register.

On reset, all GPIO pins (except for the four JTAG pins) are configured out of reset to be undriven (tristate): **GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**. Table 9-1 on page 364 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 9-2 on page 365 shows how a rising edge interrupt would be configured for pin 2 of a GPIO port.

**Table 9-1. GPIO Pad Configuration Examples**

Configuration	GPIO Register Bit Value <sup>a</sup>									
	AFSEL	DIR	ODR	DEN	PUR	PDR	DR2R	DR4R	DR8R	SLR
Digital Input (GPIO)	0	0	0	1	?	?	X	X	X	X
Digital Output (GPIO)	0	1	0	1	?	?	?	?	?	?
Open Drain Output (GPIO)	0	1	1	1	X	X	?	?	?	?
Open Drain Input/Output (I <sup>2</sup> C)	1	X	1	1	X	X	?	?	?	?
Digital Input (Timer CCP)	1	X	0	1	?	?	X	X	X	X
Digital Input (QEI)	1	X	0	1	?	?	X	X	X	X
Digital Output (PWM)	1	X	0	1	?	?	?	?	?	?
Digital Output (Timer PWM)	1	X	0	1	?	?	?	?	?	?
Digital Input/Output (SSI)	1	X	0	1	?	?	?	?	?	?
Digital Input/Output (UART)	1	X	0	1	?	?	?	?	?	?
Analog Input (Comparator)	0	0	0	0	0	0	X	X	X	X
Digital Output (Comparator)	1	X	0	1	?	?	?	?	?	?

a. X=Ignored (don't care bit)

?=Can be either 0 or 1, depending on the configuration

**Table 9-2. GPIO Interrupt Configuration Example**

Register	Desired Interrupt Event Trigger	Pin 2 Bit Value <sup>a</sup>							
		7	6	5	4	3	2	1	0
GPIOIS	0=edge 1=level	X	X	X	X	X	0	X	X
GPIOIBE	0=single edge 1=both edges	X	X	X	X	X	0	X	X
GPIOEV	0=Low level, or negative edge 1=High level, or positive edge	X	X	X	X	X	1	X	X
GPIOIM	0=masked 1=not masked	0	0	0	0	0	1	0	0

a. X=Ignored (don't care bit)

### 9.3 Register Map

Table 9-3 on page 366 lists the GPIO registers. Each GPIO port can be accessed through one of two bus apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris parts. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus. The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (APB): 0x4000.4000
- GPIO Port A (AHB): 0x4005.8000
- GPIO Port B (APB): 0x4000.5000
- GPIO Port B (AHB): 0x4005.9000
- GPIO Port C (APB): 0x4000.6000
- GPIO Port C (AHB): 0x4005.A000
- GPIO Port D (APB): 0x4000.7000
- GPIO Port D (AHB): 0x4005.B000
- GPIO Port E (APB): 0x4002.4000
- GPIO Port E (AHB): 0x4005.C000
- GPIO Port F (APB): 0x4002.5000
- GPIO Port F (AHB): 0x4005.D000
- GPIO Port G (APB): 0x4002.6000
- GPIO Port G (AHB): 0x4005.E000
- GPIO Port H (APB): 0x4002.7000
- GPIO Port H (AHB): 0x4005.F000

Note that the GPIO module clock must be enabled before the registers can be programmed (see page 237). There must be a delay of 3 system clocks after the GPIO module clock is enabled before any GPIO module registers are accessed.

**Important:** The GPIO registers in this chapter are duplicated in each GPIO block; however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to those unconnected bits has no effect, and reading those unconnected bits returns no meaningful data.

**Note:** The default reset value for the **GPIOAFSEL**, **GPIOPUR**, and **GPIODEN** registers are 0x0000.0000 for all GPIO pins, with the exception of the four JTAG/SWD pins ( $\text{PC}[3:0]$ ). These four pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for Port C is 0x0000.000F.

The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the **NMI** pin and the four JTAG/SWD pins ( $\text{PB}7$  and  $\text{PC}[3:0]$ ). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the **NMI** pin and the four JTAG/SWD pins ( $\text{PB}7$  and  $\text{PC}[3:0]$ ). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the **NMI** pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of **GPIOCR** for Port C is 0x0000.00F0.

**Table 9-3. GPIO Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	GPIODATA	R/W	0x0000.0000	GPIO Data	368
0x400	GPIODIR	R/W	0x0000.0000	GPIO Direction	369

## 9.4 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

## Register 1: GPIO Data (GPIODATA), offset 0x000

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 369).

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be High. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are 1 in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are 0 in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

### GPIO Data (GPIODATA)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (APB) base: 0x4000.6000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (APB) base: 0x4000.7000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (APB) base: 0x4002.4000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (APB) base: 0x4002.5000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (APB) base: 0x4002.6000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (APB) base: 0x4002.7000

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	R/W	0x00	GPIO Data This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and the data written to the registers are masked by the eight address lines ipaddr[9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ipaddr[9:2] and are configured as outputs. See "Data Register Operation" on page 361 for examples of reads and writes.

## Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Bits set to 1 in the **GPIODIR** register configure the corresponding pin to be an output, while bits set to 0 configure the pins to be inputs. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

### GPIO Direction (GPIODIR)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (APB) base: 0x4000.6000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (APB) base: 0x4000.7000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (APB) base: 0x4002.4000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (APB) base: 0x4002.5000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (APB) base: 0x4002.6000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (APB) base: 0x4002.7000

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x400

Type R/W, reset 0x0000.0000

### Bit/Field      Name      Type      Reset      Description

31:8      reserved      RO      0x00      Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

7:0      DIR      R/W      0x00      GPIO Data Direction  
The **DIR** values are defined as follows:

#### Value      Description

0      Pins are inputs.

1      Pins are outputs.

## Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404

The **GPIOIS** register is the interrupt sense register. Bits set to 1 in **GPIOIS** configure the corresponding pins to detect levels, while bits set to 0 configure the pins to detect edges. All bits are cleared by a reset.

### GPIO Interrupt Sense (GPIOIS)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:8            reserved            RO            0x00            Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

7:0            IS            R/W            0x00            GPIO Interrupt Sense  
The IS values are defined as follows:

#### Value Description

0    Edge on corresponding pin is detected (edge-sensitive).

1    Level on corresponding pin is detected (level-sensitive).

## Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register is the interrupt both-edges register. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 370) is set to detect edges, bits set to High in **GPIOIBE** configure the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 372). Clearing a bit configures the pin to be controlled by **GPIOIEV**. All bits are cleared by a reset.

### GPIO Interrupt Both Edges (GPIOIBE)

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x408

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IBE	R/W	0x00	GPIO Interrupt Both Edges The IBE values are defined as follows:

Value	Description
0	Interrupt generation is controlled by the <b>GPIO Interrupt Event (GPIOIEV)</b> register (see page 372).
1	Both edges on the corresponding pin trigger an interrupt.

**Note:** Single edge is determined by the corresponding bit in **GPIOIEV**.

## Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Bits set to High in **GPIOIEV** configure the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 370). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in **GPIOIS**. All bits are cleared by a reset.

### GPIO Interrupt Event (GPIOIEV)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (APB) base: 0x4000.6000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (APB) base: 0x4000.7000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (APB) base: 0x4002.4000

GPIO Port E (AHB) base: 0x4005.C000

Offset 0x40C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IEV	R/W	0x00	GPIO Interrupt Event The IEV values are defined as follows:

Value	Description
0	Falling edge or Low levels on corresponding pins trigger interrupts.
1	Rising edge or High levels on corresponding pins trigger interrupts.

## Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Bits set to High in **GPIOIM** allow the corresponding pins to trigger their individual interrupts and the combined **GPIOINTR** line. Clearing a bit disables interrupt triggering on that pin. All bits are cleared by a reset.

### GPIO Interrupt Mask (GPIOIM)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (APB) base: 0x4002.7000

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x410

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:8            reserved            RO            0x00            Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

7:0            IME            R/W            0x00            GPIO Interrupt Mask Enable  
The **IME** values are defined as follows:

#### Value Description

0    Corresponding pin interrupt is masked.

1    Corresponding pin interrupt is not masked.

## Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. Bits read High in **GPIORIS** reflect the status of interrupt trigger conditions detected (raw, prior to masking), indicating that all the requirements have been met, before they are finally allowed to trigger by the **GPIO Interrupt Mask (GPIOIM)** register (see page 373). Bits read as zero indicate that corresponding input pins have not initiated an interrupt. All bits are cleared by a reset.

### GPIO Raw Interrupt Status (GPIORIS)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (APB) base: 0x4000.6000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (APB) base: 0x4000.7000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (APB) base: 0x4002.4000

GPIO Port F (APB) base: 0x4002.5000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (APB) base: 0x4002.6000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (APB) base: 0x4002.7000

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x414

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	RIS	RO	0x00	<p>GPIO Interrupt Raw Status</p> <p>Reflects the status of interrupt trigger condition detection on pins (raw, prior to masking).</p> <p>The RIS values are defined as follows:</p>

#### Value Description

- 0 Corresponding pin interrupt requirements not met.
- 1 Corresponding pin interrupt has met requirements.

## Register 8: GPIO Masked Interrupt Status (GPIO MIS), offset 0x418

The **GPIO MIS** register is the masked interrupt status register. Bits read High in **GPIO MIS** reflect the status of input lines triggering an interrupt. Bits read as Low indicate that either no interrupt has been generated, or the interrupt is masked.

In addition to providing GPIO functionality, PB4 can also be used as an external trigger for the ADC. If PB4 is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set to 1), not only is an interrupt for PortB generated, but an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated.

If no other PortB pins are being used to generate interrupts, the **Interrupt 0-31 Set Enable (EN0)** register can disable the PortB interrupts, and the ADC interrupt can be used to read back the converted data. Otherwise, the PortB interrupt handler needs to ignore and clear interrupts on PB4, and wait for the ADC interrupt or the ADC interrupt must be disabled in the **EN0** register and the PortB interrupt handler must poll the ADC registers until the conversion is completed. See page 112 for more information.

**GPIO MIS** is the state of the interrupt after masking.

### GPIO Masked Interrupt Status (GPIO MIS)

GPIO Port A (APB) base: 0x4000.4000

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (APB) base: 0x4000.5000

GPIO Port G (APB) base: 0x4002.6000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (APB) base: 0x4002.7000

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x41C

Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IC	W1C	0x00	GPIO Interrupt Clear The IC values are defined as follows:

#### Value Description

0 Corresponding interrupt is unaffected.

1 Corresponding interrupt is cleared.

## Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420

The **GPIOAFSEL** register is the mode control select register. Writing a 1 to any bit in this register selects the hardware control for the corresponding GPIO line. All bits are cleared by a reset, therefore no GPIO line is set to hardware control by default.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 378), **GPIO Pull-Up Select (GPIOPUR)** register (see page 384), and **GPIO Digital Enable (GPIODEN)** register (see page 388) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 390) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 391) have been set to 1.

**Important:** All GPIO pins are tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**), with the exception of the four JTAG/SWD pins (PC[3:0]). The JTAG/SWD pins default to their JTAG/SWD functionality (**GPIOAFSEL=1**, **GPIODEN=1** and **GPIOPUR=1**). A Power-On-Reset (POR) or asserting RST puts both groups of pins back to their default state.

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. This may lock the debugger out of the part. This can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.**

### GPIO Alternate Function Select (GPIOAFSEL)

GPIO Port A (APB) base: 0x4000.4000

7:0	AFSEL	R/W	-	GPIO Alternate Function Select The AFSEL values are defined as follows:
Value Description				
0 Software control of corresponding GPIO line (GPIO mode).				
1 Hardware control of corresponding GPIO line (alternate hardware function).				
<b>Note:</b> The default reset value for the <b>GPIOAFSEL</b> , <b>GPIOPUR</b> , and <b>GIODEN</b> registers are 0x0000.0000 for all GPIO pins, with the exception of the four JTAG/SWD pins ( <b>PC[3:0]</b> ). These four pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for Port C is 0x0000.000F.				

## Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing a `DRV2` bit for a GPIO signal, the corresponding `DRV4` bit in the **GPIODR4R** register and the `DRV8` bit in the **GPIODR8R** register are automatically cleared by hardware.

### GPIO 2-mA Drive Select (GPIODR2R)

GPIO Port H (APB) base: 0x4002.7000

GPIO Port H (AHB) base: 0x4005.F000

Offset 0x504

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV4	R/W	0x00	Output Pad 4-mA Drive Enable A write of 1 to either <b>GPIODR2[n]</b> or <b>GPIODR8[n]</b> clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing the **DRV8** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and the **DRV4** bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

**Note:** There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the  $V_{OH}/V_{OL}$  levels. See “Recommended DC Operating Conditions” on page 810 for further information.

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV8	R/W	0x00	Output Pad 8-mA Drive Enable A write of 1 to either <b>GPIODR2[n]</b> or <b>GPIODR4[n]</b> clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 14: GPIO Open Drain Select (GPIOODR), offset 0x50C

The **GPIOODR** register is the open drain control register. Setting a bit in this register enables the open drain configuration of the corresponding GPIO pad. When open drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Input Enable (GPIODEN)** register (see page 388). Corresponding bits in the drive strength registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired rise and fall times. The GPIO acts as an open-drain input if the corresponding bit in the **GPIODIR** register is cleared. If open drain is selected while the GPIO is configured as an input, the GPIO will remain an input and the open-drain selection has no effect until the GPIO is changed to an output.

When using the I<sup>2</sup>C module, in addition to configuring the pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I<sup>2</sup>C clock and data pins should be set to 1 (see examples in “Initialization and Configuration” on page 364).

## Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510

The **GPIOPUR** register is the pull-up control register. When a bit is set to 1, it enables a weak pull-up resistor on the corresponding GPIO signal. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 386). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are set to 0 will prevent writes to the equivalent bit in this register.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin (**PB7**) and the four JTAG/SWD pins (**PC[3:0]**). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 378), **GPIO Pull-Up Select (GPIOPUR)** register (see page 384), and **GPIO Digital Enable (GPIODEN)** register (see page 388) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 390) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 391) have been set to 1.

### GPIO Pull-Up Select (GPIOPUR)

7:0      SRL      R/W      0x00      Slew Rate Limit Enable (8-mA drive only)  
The SRL values are defined as follows:

#### Value      Description

0      Slew rate control disabled.

1      Slew rate control enabled.

## Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C

**Note:** Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, with the exception of the GPIO signals used for JTAG/SWD function, all other GPIO signals are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin in a digital function (either GPIO or alternate function), the corresponding **GPIODEN** bit must be set.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 378), **GPIO Pull-Up Select (GPIOPUR)** register (see page 384), and **GPIO Digital Enable (GPIODEN)** register (see page 388) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 390) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 391) have been set to 1.

## Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 391). Writing 0x0x4C4F.434B to the **GPIOLOCK** register will unlock the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x00000001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x00000000.

### GPIO Lock (GPIOLOCK)

A read of this register returns the following values:</p>

Value	Description
0x0000.0001	locked
0x0000.0000	unlocked

## Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, and **GPIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is zero, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, or **GPIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, or **GPIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the **GPIOLOCK** register is locked.

**Important:** This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for PB7 and PC[3:0], the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins on PB7 and PC[3:0], all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, or **GPIODEN** register bits of these other pins.

### GPIO Commit (GPIOCR)

31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
7:0	CR	-	-	<p>GPIO Commit On a bit-wise basis, any bit set allows the corresponding <b>GPIOAFSEL</b>, <b>GPIOPUR</b>, or <b>GPIODEN</b> registers to be written.</p> <p><b>Note:</b> The default register type for the <b>GPIOCR</b> register is RO for all GPIO pins with the exception of the <b>NMI</b> pin and the four JTAG/SWD pins (<b>PB7</b> and <b>PC[3:0]</b>). These five pins are currently the only GPIOs that are protected by the <b>GPIOCR</b> register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.</p> <p>The default reset value for the <b>GPIOCR</b> register is 0x0000.00FF for all GPIO pins, with the exception of the <b>NMI</b> pin and the four JTAG/SWD pins (<b>PB7</b> and <b>PC[3:0]</b>). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the <b>NMI</b> pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of <b>GPIOCR</b> for GPIO Port B is 0x0000.007F while the default reset value of <b>GPIOCR</b> for Port C is 0x0000.00F0.</p>

## Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

**Important:** This register is only valid for ports D and E.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be written to 1 to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 5V source and affect analog operation, analog circuitry requires isolation from the pins when not used in their analog function.

Each bit of this register controls the isolation circuitry for circuits that share the same pin as the GPIO bit lane.

### GPIO Analog Mode Select (GPIOAMSEL)

GPIO Port A (APB) base: 0x4000.4000

# 10 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris® General-Purpose Timer Module (GPTM) contains four GPTM blocks (Timer0, Timer1, Timer 2, and Timer 3). Each GPTM block provides two 16-bit timers/counters (referred to as TimerA and TimerB) that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC).

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Stellaris microcontrollers. Other timer resources include the System Timer (SysTick) (see 97) and the PWM timer in the PWM module (see “PWM Timer” on page 727).

The General-Purpose Timers provide the following features:

- Four General-Purpose Timer Modules (GPTM), each of which provides two 16-bit timers/counters.  
Each GPTM can be configured to operate independently:
  - As a single 32-bit timer
  - As one 32-bit Real-Time Clock (RTC) to event capture
  - For Pulse Width Modulation (PWM)
  - To trigger analog-to-digital conversions
- 32-bit Timer modes
  - Programmable one-shot timer
  - Programmable periodic timer
  - Real-Time Clock when using an external 32.768-KHz clock as the input
  - User-enabled stalling when the controller asserts CPU Halt flag during debug
  - ADC event trigger
- 16-bit Timer modes
  - General-purpose timer function with an 8-bit prescaler (for one-shot and periodic modes only)
  - Programmable one-shot timer
  - Programmable periodic timer
  - User-enabled stalling when the controller asserts CPU Halt flag during debug
  - ADC event trigger
- 16-bit Input Capture modes
  - Input edge count capture

- Input edge time capture
- 16-bit PWM mode
  - Simple PWM mode with software-programmable output inversion of the PWM signal

## 10.1 Block Diagram

**Note:** In Figure 10-1 on page 408, the specific CCP pins available depend on the Stellaris device. See Table 10-1 on page 408 for the available CCPs.

**Figure 10-1. GPTM Module Block Diagram**

**Table 10-1. Available CCP Pins**

Timer	16-Bit Up/Down Counter	Even CCP Pin	Odd CCP Pin
Timer 0	TimerA	CCP0	-
	TimerB	-	CCP1
Timer 1	TimerA	CCP2	-
	TimerB	-	CCP3
Timer 2	TimerA	CCP4	-
	TimerB	-	CCP5
Timer 3	TimerA	CCP6	-
	TimerB	-	CCP7

## 10.2 Functional Description

The main components of each GPTM block are two free-running 16-bit up/down counters (referred to as TimerA and TimerB), two 16-bit match registers, and two 16-bit load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface.

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 419), the **GPTM TimerA Mode (GPTMTAMR)** register (see page 420), and the **GPTM TimerB Mode (GPTMTBMR)** register (see page 422). When in one of the 32-bit modes, the timer can only act as a 32-bit timer. However, when configured in 16-bit mode, the GPTM can have its two 16-bit timers configured in any combination of the 16-bit modes.

### 10.2.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters TimerA and TimerB are initialized to 0xFFFF, along with their corresponding load registers: the **GPTM TimerA Interval Load (GPTMTAILR)** register (see page 433) and the **GPTM TimerB Interval Load (GPTMTBILR)** register (see page 434). The prescale counters are initialized to 0x00: the **GPTM TimerA Prescale (GPTMTAPR)** register (see page 437) and the **GPTM TimerB Prescale (GPTMTBPR)** register (see page 438).

### 10.2.2 32-Bit Timer Operating Modes

This section describes the three GPTM 32-bit timer modes (One-Shot, Periodic, and RTC) and their configuration.

The GPTM is placed into 32-bit mode by writing a 0 (One-Shot/Periodic 32-bit timer mode) or a 1 (RTC mode) to the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM TimerA Interval Load (GPTMTAILR)** register [15:0], see page 433
- **GPTM TimerB Interval Load (GPTMTBILR)** register [15:0], see page 434
- **GPTM TimerA (GPTMTAR)** register [15:0], see page 439
- **GPTM TimerB (GPTMTBR)** register [15:0], see page 440

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0] : GPTMTAILR[15:0]
```

Likewise, a read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0] : GPTMTAR[15:0]
```

#### 10.2.2.1 32-Bit One-Shot/Periodic Timer Mode

In 32-bit one-shot and periodic timer modes, the concatenated versions of the TimerA and TimerB registers are configured as a 32-bit down-counter. The selection of one-shot or periodic mode is determined by the value written to the TAMR field of the **GPTM TimerA Mode (GPTMTAMR)** register (see page 420), and there is no need to write to the **GPTM TimerB Mode (GPTMTBMR)** register.

When software writes the **TAEN** bit in the **GPTM Control (GPTMCTL)** register (see page 424), the timer begins counting down from its preloaded value. Once the 0x0000.0000 state is reached, the timer reloads its start value from the concatenated **GPTMTAILR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the **TAEN** bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting.

In addition to reloading the count value, the GPTM generates interrupts and triggers when it reaches the 0x000.0000 state. The GPTM sets the **TATORIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 429), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 431). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 427), the GPTM also sets the **TATOMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 430). The ADC trigger is enabled by setting the **TAOTE** bit in **GPTMCTL**.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the **TASTALL** bit in the **GPTMCTL** register is set, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution.

### 10.2.2.2 32-Bit Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the TimerA and TimerB registers are configured as a 32-bit up-counter. When RTC mode is selected for the first time, the counter is loaded with a value of 0x0000.0001. All subsequent load values must be written to the **GPTM TimerA Match (GPTMTAMATCHR)** register (see page 435) by the controller.

The input clock on an even CCP input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1 Hz rate and is passed along to the input of the 32-bit counter.

When software writes the **TAEN** bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x0000.0001. When the current count value matches the preloaded value in the **GPTMTAMATCHR** register, it rolls over to a value of 0x0000.0000 and continues counting until either a hardware reset, or it is disabled by software (clearing the **TAEN** bit). When a match occurs, the GPTM asserts the **RTCRIS** bit in **GPTMRIS**. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the **RTCMIS** bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

If the **TASTALL** and/or **TBSTALL** bits in the **GPTMCTL** register are set, the timer does not freeze if the **RTCEN** bit is set in **GPTMCTL**.

### 10.2.3 16-Bit Timer Operating Modes

The GPTM is placed into global 16-bit mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 419). This section describes each of the GPTM 16-bit modes of operation. TimerA and TimerB have identical modes, so a single description is given using an **n** to reference both.

#### 10.2.3.1 16-Bit One-Shot/Periodic Timer Mode

In 16-bit one-shot and periodic timer modes, the timer is configured as a 16-bit down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. The selection of one-shot or periodic mode is determined by the value written to the **TnMR** field of the **GPTMTnMR** register. The optional prescaler is loaded into the **GPTM Timern Prescale (GPTMTnPR)** register.

When software writes the TnEN bit in the **GPTMCTL** register, the timer begins counting down from its preloaded value. Once the 0x0000 state is reached, the timer reloads its start value from **GPTMTnILR** and **GPTMTnPR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the TnEN bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting.

In addition to reloading the count value, the timer generates interrupts and triggers when it reaches the 0x0000 state. The GPTM sets the TnTORIS bit in the **GPTMRIS** register, and holds it until it is cleared by writing the **GPTMICR** register. If the time-out interrupt is enabled in **GPTMIMR**, the GPTM also sets the TnTOMIS bit in **GPTMISR** and generates a controller interrupt. The ADC trigger is enabled by setting the TnOTE bit in the **GPTMCTL** register.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the TnSTALL bit in the **GPTMCTL** register is set, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution.

The following example shows a variety of configurations for a 16-bit free running timer while using the prescaler. All values assume a 50-MHz clock with Tc=20 ns (clock period).

**Table 10-2. 16-Bit Timer With Prescaler Configurations**

Prescale	#Clock (T c) <sup>a</sup>	Max Time	Units
00000000	1	1.3107	μs
00000001	2	2.6214	μs
00000010	3	3.9322	μs
-----	--	--	--
11111101	254	332.9229	μs
11111110	255	334.2336	μs
11111111	256	335.5443	μs

a. Tc is the clock period.

### 10.2.3.2 16-Bit Input Edge Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

**Note:** The prescaler is not available in 16-Bit Input Edge Count mode.

In Edge Count mode, the timer is configured as a down-counter capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge Count mode, the TnCMR bit of the **GPTMTnMR** register must be set to 0. The type of edge that the timer counts is determined by the TnEVENT fields of the **GPTMCTL** register. During initialization, the **GPTM Timern Match (GPTMTnMATCHR)** register is configured so that the difference between the value in the **GPTMTnILR** register and the **GPTMTnMATCHR** register equals the number of edge events that must be counted.

When software writes the TnEN bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements the counter by 1 until the event count matches **GPTMTnMATCHR**. When the counts match, the GPTM asserts the CnMRIS bit in the **GPTMRIS** register (and the CnMMIS bit, if the interrupt is not masked).

The counter is then reloaded using the value in **GPTMTnILR**, and stopped since the GPTM automatically clears the TnEN bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until TnEN is re-enabled by software.

Figure 10-2 on page 412 shows how input edge count mode works. In this case, the timer start value is set to **GPTMTnILR** =0x000A and the match value is set to **GPTMTnMATCHR** =0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted since the timer automatically clears the TnEN bit after the current count matches the value in the **GPTMTnMATCHR** register.

**Figure 10-2. 16-Bit Input Edge Count Mode Example**

#### 10.2.3.3 16-Bit Input Edge Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

**Note:** The prescaler is not available in 16-Bit Input Edge Time mode.

In Edge Time mode, the timer is configured as a free-running down-counter initialized to the value loaded in the **GPTMTnILR** register (or 0xFFFF at reset). This mode allows for event capture of either rising or falling edges, but not both. The timer is placed into Edge Time mode by setting the TnCMR bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the TnEVENT fields of the **GPTMCTL** register.

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current Tn counter value is captured in the **GPTMTnR** register and is available to be read by the controller. The GPTM then asserts the CnERIS bit (and the CnEMIS bit, if the interrupt is not masked).

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the 0x0000 state, it is reloaded with the value from the **GPTMTnILR** register.

Figure 10-3 on page 413 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** register, and is held there until another rising edge is detected (at which point the new count value is loaded into **GPTMTnR**).

**Figure 10-3. 16-Bit Input Edge Time Mode Example**

#### 10.2.3.4 16-Bit PWM Mode

**Note:** The prescaler is not available in 16-Bit PWM mode.

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a down-counter with a start value (and thus period) defined by **GPTMTnILR**. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x2.

When software writes the **TnEN** bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0000 state. On the next counter cycle, the counter reloads its start value from **GPTMTnILR** and continues counting until disabled by software clearing the **TnEN** bit in the **GPTMCTL** register. No interrupts or status bits are asserted in PWM mode.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** register (its start state), and is deasserted when the counter value equals the value in the **GPTM Timern Match Register (GPTMTnMATCHR)**. Software has the capability of inverting the output PWM signal by setting the **TnPWML** bit in the **GPTMCTL** register.

Figure 10-4 on page 414 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML**=0 (duty cycle would be 33% for the **TnPWML**=1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

**Figure 10-4. 16-Bit PWM Mode Example**

## 10.3 Initialization and Configuration

To use the general-purpose timers, the peripheral clock must be enabled by setting the TIMER0, TIMER1, TIMER2, and TIMER3 bits in the **RCGC1** register.

This section shows module initialization and configuration examples for each of the supported timer modes.

### 10.3.1 32-Bit One-Shot/Periodic Timer Mode

The GPTM is configured for 32-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TAEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0.
3. Set the **TAMR** field in the **GPTM TimerA Mode Register (GPTMTAMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Load the start value into the **GPTM TimerA Interval Load Register (GPTMTAILR)**.
5. If interrupts are required, set the **TATOIM** bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the **TAEN** bit in the **GPTMCTL** register to enable the timer and start counting.

7. Poll the TATORIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the TATOCINT bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

In One-Shot mode, the timer stops counting after step 7 on page 415. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

### 10.3.2 32-Bit Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the TAEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x1.
3. Write the desired match value to the **GPTM TimerA Match Register (GPTMTAMATCHR)**.
4. Set/clear the RTCCEN bit in the **GPTM Control Register (GPTMCTL)** as desired.
5. If interrupts are required, set the RTCIM bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the TAEN bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTAMATCHR** register, the GPTM asserts the RTCRIS bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the RTCCINT bit in the **GPTMICR** register.

### 10.3.3 16-Bit One-Shot/Periodic Timer Mode

A timer is configured for 16-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x4.
3. Set the TnMR field in the **GPTM Timer Mode (GPTMTnMR)** register:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. If a prescaler is to be used, write the prescale value to the **GPTM Timern Prescale Register (GPTMTnPR)**.
5. Load the start value into the **GPTM Timer Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the TnTOIM bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the TnEN bit in the **GPTM Control Register (GPTMCTL)** to enable the timer and start counting.
8. Poll the TnTORIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the TnTOCINT bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

In One-Shot mode, the timer stops counting after step 8 on page 415. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

#### 10.3.4 16-Bit Input Edge Count Mode

A timer is configured to Input Edge Count mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to 0x0 and the `TnMR` field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timern Interval Load (GPTMTnILR)** register.
6. Load the desired event count into the **GPTM Timern Match (GPTMTnMATCHR)** register.
7. If interrupts are required, set the `CnMIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the `TnEN` bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
9. Poll the `CnMRIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnMCINT` bit of the **GPTM Interrupt Clear (GPTMICR)** register.

In Input Edge Count Mode, the timer stops after the desired number of edge events has been detected. To re-enable the timer, ensure that the `TnEN` bit is cleared and repeat step 4 on page 416 through step 9 on page 416.

#### 10.3.5 16-Bit Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to 0x1 and the `TnMR` field to 0x3.
4. Configure the type of event that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timern Interval Load (GPTMTnILR)** register.
6. If interrupts are required, set the `CnEIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the `TnEN` bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
8. Poll the `CnERIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnECINT` bit of the **GPTM**

**Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timern (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

### 10.3.6 16-Bit PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the `TnAMS` bit to 0x1, the `TnCMR` bit to 0x0, and the `TnMR` field to 0x2.
4. Configure the output state of the PWM signal (whether or not it is inverted) in the `TnPWL` field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timern Interval Load (GPTMTnILR)** register.
6. Load the **GPTM Timern Match (GPTMTnMATCHR)** register with the desired value.
7. Set the `TnEN` bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

## 10.4 Register Map

Table 10-3 on page 417 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- Timer0: 0x4003.0000
- Timer1: 0x4003.1000
- Timer2: 0x4003.2000
- Timer3: 0x4003.3000

Note that the Timer module clock must be enabled before the registers can be programmed (see page 228). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

**Table 10-3. Timers Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	GPTMCFG	R/W	0x0000.0000	GPTM Configuration	419
0x004	GPTMTAMR	R/W	0x0000.0000	GPTM TimerA Mode	420
0x008	GPTMTBMR	R/W	0x0000.0000	GPTM TimerB Mode	422

**Table 10-3. Timers Register Map (*continued*)**

Offset	Name	Type	Reset	Description	See page
0x00C	GPTMCTL	R/W	0x0000.0000	GPTM Control	424
0x018	GPTMIMR	R/W	0x0000.0000	GPTM Interrupt Mask	427
0x01C	GPTMRIS	RO	0x0000.0000	GPTM Raw Interrupt Status	429
0x020	GPTMMIS	RO	0x0000.0000	GPTM Masked Interrupt Status	430
0x024	GPTMICR	W1C	0x0000.0000	GPTM Interrupt Clear	431
0x028	GPTMTAILR	R/W	0xFFFF.FFFF	GPTM TimerA Interval Load	433

0x034	GPTMTBMATCHR	R/W	0x0000.FFFF	GPTM TimerB Match	436
0x038	GPTMTAPR	R/W	0x0000.0000	GPTM TimerA Prescale	437
0x03C	GPTMTBPR	R/W	0x0000.0000	GPTM TimerB Prescale	438
0x048	GPTMTAR	RO	0xFFFF.FFFF	GPTM TimerA	439
0x04C	GPTMTBR	RO	0x0000.FFFF	GPTM TimerB	440

## 10.5 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

## Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

### GPTM Configuration (GPTMCFG)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description												
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.												
2:0	GPTMCFG	R/W	0x0	<p>GPTM Configuration</p> <p>The GPTMCFG values are defined as follows:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>32-bit timer configuration.</td> </tr> <tr> <td>0x1</td> <td>32-bit real-time clock (RTC) counter configuration.</td> </tr> <tr> <td>0x2</td> <td>Reserved</td> </tr> <tr> <td>0x3</td> <td>Reserved</td> </tr> <tr> <td>0x4-0x7</td> <td>16-bit timer configuration, function is controlled by bits 1:0 of <b>GPTMTAMR</b> and <b>GPTMTBMR</b>.</td> </tr> </tbody> </table>	Value	Description	0x0	32-bit timer configuration.	0x1	32-bit real-time clock (RTC) counter configuration.	0x2	Reserved	0x3	Reserved	0x4-0x7	16-bit timer configuration, function is controlled by bits 1:0 of <b>GPTMTAMR</b> and <b>GPTMTBMR</b> .
Value	Description															
0x0	32-bit timer configuration.															
0x1	32-bit real-time clock (RTC) counter configuration.															
0x2	Reserved															
0x3	Reserved															
0x4-0x7	16-bit timer configuration, function is controlled by bits 1:0 of <b>GPTMTAMR</b> and <b>GPTMTBMR</b> .															

## Register 2: GPTM TimerA Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the **TAAMS** bit to 0x1, the **TACMR** bit to 0x0, and the **TAMR** field to 0x2.

### GPTM TimerA Mode (GPTMTAMR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
3	TAAMS	R/W	0	GPTM TimerA Alternate Mode Select The <b>TAAMS</b> values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Capture mode is enabled.</td> </tr> <tr> <td>1</td> <td>PWM mode is enabled.</td> </tr> </tbody> </table> <b>Note:</b> To enable PWM mode, you must also clear the <b>TACMR</b> bit and set the <b>TAMR</b> field to 0x2.	Value	Description	0	Capture mode is enabled.	1	PWM mode is enabled.
Value	Description									
0	Capture mode is enabled.									
1	PWM mode is enabled.									
2	TACMR	R/W	0	GPTM TimerA Capture Mode The <b>TACMR</b> values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Edge-Count mode</td> </tr> <tr> <td>1</td> <td>Edge-Time mode</td> </tr> </tbody> </table>	Value	Description	0	Edge-Count mode	1	Edge-Time mode
Value	Description									
0	Edge-Count mode									
1	Edge-Time mode									

Bit/Field	Name	Type	Reset	Description										
1:0	TAMR	R/W	0x0	GPTM TimerA Mode The TAMR values are defined as follows:  <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Reserved</td></tr><tr><td>0x1</td><td>One-Shot Timer mode</td></tr><tr><td>0x2</td><td>Periodic Timer mode</td></tr><tr><td>0x3</td><td>Capture mode</td></tr></tbody></table> The Timer mode is based on the timer configuration defined by bits 2:0 in the <b>GPTMCFG</b> register (16-or 32-bit). In 16-bit timer configuration, TAMR controls the 16-bit timer modes for TimerA. In 32-bit timer configuration, this register controls the mode and the contents of <b>GPTMTBMR</b> are ignored.	Value	Description	0x0	Reserved	0x1	One-Shot Timer mode	0x2	Periodic Timer mode	0x3	Capture mode
Value	Description													
0x0	Reserved													
0x1	One-Shot Timer mode													
0x2	Periodic Timer mode													
0x3	Capture mode													

### Register 3: GPTM TimerB Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the **TBAMS** bit to 0x1, the **TBCMR** bit to 0x0, and the **TBMR** field to 0x2.

#### GPTM TimerB Mode (GPTMTBMR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000

 Timer3 base: 0x4003.3000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TBAMS	R/W	0	GPTM TimerB Alternate Mode Select The <b>TBAMS</b> values are defined as follows:  Value Description 0 Capture mode is enabled. 1 PWM mode is enabled.  <b>Note:</b> To enable PWM mode, you must also clear the <b>TBCMR</b> bit and set the <b>TBMR</b> field to 0x2.
2	TBCMR	R/W	0	GPTM TimerB Capture Mode The <b>TBCMR</b> values are defined as follows:  Value Description 0 Edge-Count mode 1 Edge-Time mode

Bit/Field	Name	Type	Reset	Description										
1:0	TBMR	R/W	0x0	GPTM TimerB Mode The TBMR values are defined as follows:  <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Reserved</td></tr><tr><td>0x1</td><td>One-Shot Timer mode</td></tr><tr><td>0x2</td><td>Periodic Timer mode</td></tr><tr><td>0x3</td><td>Capture mode</td></tr></tbody></table> The timer mode is based on the timer configuration defined by bits 2:0 in the <b>GPTMCFG</b> register. In 16-bit timer configuration, these bits control the 16-bit timer modes for TimerB. In 32-bit timer configuration, this register's contents are ignored and <b>GPTMTAMR</b> is used.	Value	Description	0x0	Reserved	0x1	One-Shot Timer mode	0x2	Periodic Timer mode	0x3	Capture mode
Value	Description													
0x0	Reserved													
0x1	One-Shot Timer mode													
0x2	Periodic Timer mode													
0x3	Capture mode													

## Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

Value	Description													
0	TimerA is disabled.													
1	TimerA is enabled and begins counting or the capture logic is enabled based on the <code>GPTMCFG</code> register.													

## Register 5: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Writing a 1 enables the interrupt, while writing a 0 disables it.

### GPTM Interrupt Mask (GPTMIMR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x018

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	CBEIM	R/W	0	GPTM CaptureB Event Interrupt Mask The CBEIM values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.
9	CBMIM	R/W	0	GPTM CaptureB Match Interrupt Mask The CBMIM values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.
8	TBTOIM	R/W	0	GPTM TimerB Time-Out Interrupt Mask The TBTOIM values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.
7:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
3	RTCIM	R/W	0	GPTM RTC Interrupt Mask The <code>RTCIM</code> values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.
2	CAEIM	R/W	0	GPTM CaptureA Event Interrupt Mask The <code>CAEIM</code> values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.
1	CAMIM	R/W	0	GPTM CaptureA Match Interrupt Mask The <code>CAMIM</code> values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.
0	TATOIM	R/W	0	GPTM TimerA Time-Out Interrupt Mask The <code>TATOIM</code> values are defined as follows:  Value Description 0 Interrupt is disabled. 1 Interrupt is enabled.

## Register 6: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

### GPTM Raw Interrupt Status (GPTMRIS)

Timer0 base: 0x4003.0000  
Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000  
Timer3 base: 0x4003.3000  
Offset 0x01C  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	CBERIS	RO	0	GPTM CaptureB Event Raw Interrupt This is the CaptureB Event interrupt status prior to masking.
9	CBMRIS	RO	0	GPTM CaptureB Match Raw Interrupt This is the CaptureB Match interrupt status prior to masking.
8	TBTORIS	RO	0	GPTM TimerB Time-Out Raw Interrupt This is the TimerB time-out interrupt status prior to masking.
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RTCRIS	RO	0	GPTM RTC Raw Interrupt This is the RTC Event interrupt status prior to masking.
2	CAERIS	RO	0	GPTM CaptureA Event Raw Interrupt This is the CaptureA Event interrupt status prior to masking.
1	CAMRIS	RO	0	GPTM CaptureA Match Raw Interrupt This is the CaptureA Match interrupt status prior to masking.
0	TATORIS	RO	0	GPTM TimerA Time-Out Raw Interrupt This is the TimerA time-out interrupt status prior to masking.

## Register 7: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register shows the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

### GPTM Masked Interrupt Status (GPTMMIS)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x020

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	CBEMIS	RO	0	GPTM CaptureB Event Masked Interrupt This is the CaptureB event interrupt status after masking.
9	CBMMIS	RO	0	GPTM CaptureB Match Masked Interrupt This is the CaptureB match interrupt status after masking.
8	TBTOMIS	RO	0	GPTM TimerB Time-Out Masked Interrupt This is the TimerB time-out interrupt status after masking.
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RTCMIS	RO	0	GPTM RTC Masked Interrupt This is the RTC event interrupt status after masking.
2	CAEMIS	RO	0	GPTM CaptureA Event Masked Interrupt This is the CaptureA event interrupt status after masking.
1	CAMMIS	RO	0	GPTM CaptureA Match Masked Interrupt This is the CaptureA match interrupt status after masking.
0	TATOMIS	RO	0	GPTM TimerA Time-Out Masked Interrupt This is the TimerA time-out interrupt status after masking.

## Register 8: GPTM Interrupt Clear (GPTMICR), offset 0x024

This register is used to clear the status bits in the **GPTMRIS** and **GPTMMIS** registers. Writing a 1 to a bit clears the corresponding bit in the **GPTMRIS** and **GPTMMIS** registers.

### GPTM Interrupt Clear (GPTMICR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x024  
 Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	CBECINT	W1C	0	GPTM CaptureB Event Interrupt Clear The CBECINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.
9	CBMCINT	W1C	0	GPTM CaptureB Match Interrupt Clear The CBMCINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.
8	TBTOCINT	W1C	0	GPTM TimerB Time-Out Interrupt Clear The TBTOCINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
3	RTCCINT	W1C	0	GPTM RTC Interrupt Clear The RTCCINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.
2	CAECINT	W1C	0	GPTM CaptureA Event Interrupt Clear The CAECINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.
1	CAMCINT	W1C	0	GPTM CaptureA Match Interrupt Clear The CAMCINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.
0	TATOCINT	W1C	0	GPTM TimerA Time-Out Interrupt Clear The TATOCINT values are defined as follows:  Value Description 0 The interrupt is unaffected. 1 The interrupt is cleared.

## Register 9: GPTM TimerA Interval Load (GPTMTAILR), offset 0x028

This register is used to load the starting count value into the timer. When GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM TimerB Interval Load (GPTMTBILR)** register). In 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

### GPTM TimerA Interval Load (GPTMTAILR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x028

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	TAILRH	R/W	0xFFFF	GPTM TimerA Interval Load Register High When configured for 32-bit mode via the <b>GPTMCFG</b> register, the <b>GPTM TimerB Interval Load (GPTMTBILR)</b> register loads this value on a write. A read returns the current value of <b>GPTMTBILR</b> . In 16-bit mode, this field reads as 0 and does not have an effect on the state of <b>GPTMTBILR</b> .
15:0	TAILRL	R/W	0xFFFF	GPTM TimerA Interval Load Register Low For both 16- and 32-bit modes, writing this field loads the counter for TimerA. A read returns the current value of <b>GPTMTAILR</b> .

## Register 10: GPTM TimerB Interval Load (GPTMTBILR), offset 0x02C

This register is used to load the starting count value into TimerB. When the GPTM is configured to a 32-bit mode, **GPTMTBILR** returns the current value of TimerB and ignores writes.

GPTM TimerB Interval Load (GPTMTBILR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x02C  
 Type R/W, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBILRL	R/W	0xFFFF	GPTM TimerB Interval Load Register When the GPTM is not configured as a 32-bit timer, a write to this field updates <b>GPTMTBILR</b> . In 32-bit mode, writes are ignored, and reads return the current value of <b>GPTMTBILR</b> .

## Register 11: GPTM TimerA Match (GPTMTAMATCHR), offset 0x030

This register is used in 32-bit Real-Time Clock mode and 16-bit PWM and Input Edge Count modes.

### GPTM TimerA Match (GPTMTAMATCHR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x030

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	TAMRH	R/W	0xFFFF	<p>GPTM TimerA Match Register High</p> <p>When configured for 32-bit Real-Time Clock (RTC) mode via the <b>GPTMCFG</b> register, this value is compared to the upper half of <b>GPTMTAR</b>, to determine match events.</p> <p>In 16-bit mode, this field reads as 0 and does not have an effect on the state of <b>GPTMTBMATCHR</b>.</p>
15:0	TAMRL	R/W	0xFFFF	<p>GPTM TimerA Match Register Low</p> <p>When configured for 32-bit Real-Time Clock (RTC) mode via the <b>GPTMCFG</b> register, this value is compared to the lower half of <b>GPTMTAR</b>, to determine match events.</p> <p>When configured for PWM mode, this value along with <b>GPTMTAILR</b>, determines the duty cycle of the output PWM signal.</p> <p>When configured for Edge Count mode, this value along with <b>GPTMTAILR</b>, determines how many edge events are counted. The total number of edge events counted is equal to the value in <b>GPTMTAILR</b> minus this value.</p>

## Register 12: GPTM TimerB Match (GPTMTBMATCHR), offset 0x034

This register is used in 16-bit PWM and Input Edge Count modes.

### GPTM TimerB Match (GPTMTBMATCHR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x034

Type R/W, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBMRL	R/W	0xFFFF	GPTM TimerB Match Register Low When configured for PWM mode, this value along with <b>GPTMTBILR</b> , determines the duty cycle of the output PWM signal. When configured for Edge Count mode, this value along with <b>GPTMTBILR</b> , determines how many edge events are counted. The total number of edge events counted is equal to the value in <b>GPTMTBILR</b> minus this value.

## Register 13: GPTM TimerA Prescale (GPTMTAPR), offset 0x038

This register allows software to extend the range of the 16-bit timers when operating in one-shot or periodic mode.

### GPTM TimerA Prescale (GPTMTAPR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x038

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	TAPSR	R/W	0x00	<b>GPTM TimerA Prescale</b> The register loads this value on a write. A read returns the current value of the register. Refer to Table 10-2 on page 411 for more details and an example.

## Register 14: GPTM TimerB Prescale (GPTMTBPR), offset 0x03C

This register allows software to extend the range of the 16-bit timers when operating in one-shot or periodic mode.

### GPTM TimerB Prescale (GPTMTBPR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x03C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	TBPSR	R/W	0x00	GPTM TimerB Prescale The register loads this value on a write. A read returns the current value of this register. Refer to Table 10-2 on page 411 for more details and an example.

## Register 15: GPTM TimerA (GPTMTAR), offset 0x048

This register shows the current value of the TimerA counter in all cases except for Input Edge Count mode. When in this mode, this register contains the number of edges that have occurred.

### GPTM TimerA (GPTMTAR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x048

Type RO, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	TARH	RO	0xFFFF	GPTM TimerA Register High If the <b>GPTMCFG</b> is in a 32-bit mode, TimerB value is read. If the <b>GPTMCFG</b> is in a 16-bit mode, this is read as zero.
15:0	TARL	RO	0xFFFF	GPTM TimerA Register Low A read returns the current value of the <b>GPTM TimerA Count Register</b> , except in Input Edge-Count mode, when it returns the number of edges that have occurred.

## Register 16: GPTM TimerB (GPTMTBR), offset 0x04C

This register shows the current value of the TimerB counter in all cases except for Input Edge Count mode. When in this mode, this register contains the number of edges that have occurred.

### GPTM TimerB (GPTMTBR)

Timer0 base: 0x4003.0000

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x04C

Type RO, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBRL	RO	0xFFFF	GPTM TimerB A read returns the current value of the <b>GPTM TimerB Count Register</b> , except in Input Edge-Count mode, when it returns the number of edges that have occurred.

## 11 Watchdog Timer

A watchdog timer can generate nonmaskable interrupts (NMIs) or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way.

The Stellaris® Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the controller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 11.1 Block Diagram

Figure 11-1. WDT Module Block Diagram

## 11.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled (via the `WatchdogResetEnable` function), the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

## 11.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **WDT** bit in the **RCGC0** register. The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If the Watchdog is configured to trigger system resets, set the **RESEN** bit in the **WDTCTL** register.
3. Set the **INTEN** bit in the **WDTCTL** register to enable the Watchdog and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

## 11.4 Register Map

Table 11-1 on page 443 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address of 0x4000.0000.

**Table 11-1. Watchdog Timer Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	WDTLOAD	R/W	0xFFFF.FFFF	Watchdog Load	445
0x004	WDTVALUE	RO	0xFFFF.FFFF	Watchdog Value	446

## 11.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

## Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

### Watchdog Load (WDTLOAD)

Base 0x4000.0000

Offset 0x000

Type R/W, reset 0xFFFF.FFFF

Bit/Field                  Name                  Type                  Reset                  Description

31:0                  WDTLoad                  R/W                  0xFFFF.FFFF                  Watchdog Load Value

**Register 2: Watchdog Value (WDTVALUE), offset 0x004**

This register contains the current count value of the timer.

## Watchdog Value (WDTVALUE)

Base 0x4000.0000  
Offset 0x004  
Type RO, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	WDTValue	RO	0xFFFF.FFFF	Watchdog Value Current value of the 32-bit down counter.
------	----------	----	-------------	---

## Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled, all subsequent writes to the control register are ignored. The only mechanism that can re-enable writes is a hardware reset.

### Watchdog Control (WDTCTL)

Base 0x4000.0000  
Offset 0x008  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	RESEN	R/W	0	Watchdog Reset Enable The RESEN values are defined as follows:  Value Description 0 Disabled. 1 Enable the Watchdog module reset output.
0	INTEN	R/W	0	Watchdog Interrupt Enable The INTEN values are defined as follows:  Value Description 0 Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset). 1 Interrupt event enabled. Once enabled, all writes are ignored.

## Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Value for a read or reset is indeterminate.

Watchdog Interrupt Clear (WDTICR)

Base 0x4000.0000

Offset 0x00C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	WDTIntClr	WO	-	Watchdog Interrupt Clear

## Register 5: Watchdog Raw Interrupt Status (WDTRIS), offset 0x010

This register is the raw interrupt status register. Watchdog interrupt events can be monitored via this register if the controller interrupt is masked.

Watchdog Raw Interrupt Status (WDTRIS)

Base 0x4000.0000  
Offset 0x010  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WDTRIS	RO	0	Watchdog Raw Interrupt Status Gives the raw interrupt state (prior to masking) of <b>WDTINTR</b> .

## Register 6: Watchdog Masked Interrupt Status (WDTMIS), offset 0x014

This register is the masked interrupt status register. The value of this register is the logical AND of the raw interrupt bit and the Watchdog interrupt enable bit.

### Watchdog Masked Interrupt Status (WDTMIS)

Base 0x4000.0000  
Offset 0x014  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WDTMIS	RO	0	Watchdog Masked Interrupt Status Gives the masked interrupt state (after masking) of the <b>WDTINTR</b> interrupt.

## Register 7: Watchdog Test (WDTTEST), offset 0x418

This register provides user-enabled stalling when the microcontroller asserts the CPU halt flag during debug.

### Watchdog Test (WDTTEST)

Base 0x4000.0000  
Offset 0x418  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	STALL	R/W	0	Watchdog Stall Enable When set to 1, if the Stellaris microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

### Watchdog Lock (WDTLOCK)

Base 0x4000.0000  
Offset 0xC00  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description						
31:0	WDTLock	R/W	0x0000	<p>Watchdog Lock</p> <p>A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value re-applies the lock, preventing any register updates.</p> <p>A read of this register returns the following values:</p> <table> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0000.0001</td> <td>Locked</td> </tr> <tr> <td>0x0000.0000</td> <td>Unlocked</td> </tr> </tbody> </table>	Value	Description	0x0000.0001	Locked	0x0000.0000	Unlocked
Value	Description									
0x0000.0001	Locked									
0x0000.0000	Unlocked									

## Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 4 (WDTPeriphID4)

Base 0x4000.0000  
Offset 0xFD0  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID4	RO	0x00	WDT Peripheral ID Register[7:0]

## Register 10: Watchdog Peripheral Identification 5 (WDTPeriphID5), offset 0xFD4

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 5 (WDTPeriphID5)

Base 0x4000.0000  
Offset 0xFD4  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID5	RO	0x00	WDT Peripheral ID Register[15:8]

## Register 11: Watchdog Peripheral Identification 6 (WDTPeriphID6), offset 0xFD8

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 6 (WDTPeriphID6)

Base 0x4000.0000

Offset 0xFD8

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID6	RO	0x00	WDT Peripheral ID Register[23:16]

## Register 12: Watchdog Peripheral Identification 7 (WDTPeriphID7), offset 0xFDC

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 7 (WDTPeriphID7)

Base 0x4000.0000  
Offset 0xFDC  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID7	RO	0x00	WDT Peripheral ID Register[31:24]

## Register 13: Watchdog Peripheral Identification 0 (WDTPeriphID0), offset 0xFE0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 0 (WDTPeriphID0)

Base 0x4000.0000  
Offset 0xFE0  
Type RO, reset 0x0000.0005

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID0	RO	0x05	Watchdog Peripheral ID Register[7:0]

## Register 14: Watchdog Peripheral Identification 1 (WDTPeriphID1), offset 0xFE4

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 1 (WDTPeriphID1)

Base 0x4000.0000  
Offset 0xFE4  
Type RO, reset 0x0000.0018

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID1	RO	0x18	Watchdog Peripheral ID Register[15:8]

## Register 15: Watchdog Peripheral Identification 2 (WDTPeriphID2), offset 0xFE8

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 2 (WDTPeriphID2)

Base 0x4000.0000  
Offset 0xFE8  
Type RO, reset 0x0000.0018

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID2	RO	0x18	Watchdog Peripheral ID Register[23:16]

## Register 16: Watchdog Peripheral Identification 3 (WDTPeriphID3), offset 0xFEC

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### Watchdog Peripheral Identification 3 (WDTPeriphID3)

Base 0x4000.0000  
Offset 0xFEC

## 12 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number.

The Stellaris® ADC module features 10-bit conversion resolution and supports eight input channels, plus an internal temperature sensor. The ADC module contains four programmable sequencer which allows for the sampling of multiple analog input sources without controller intervention. Each sample sequence provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequence priority.

The Stellaris ADC module provides the following features:

- Eight analog input channels
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Sample rate of one million samples/second
- Flexible, configurable analog-to-digital conversion
- Four programmable sample conversion sequences from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples for improved accuracy
- Converter uses an internal 3-V reference
- Power and ground for the analog circuitry is separate from the digital power and ground

### 12.1 Block Diagram

Figure 12-1 on page 466 provides details on the internal configuration of the ADC controls and data registers.

**Figure 12-1. ADC Module Block Diagram**

## 12.2 Functional Description

The Stellaris ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the controller. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence.

### 12.2.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 12-1 on page 466 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. In this implementation, each FIFO entry is a 32-bit word, with the lower 10 bits containing the conversion result.

**Table 12-1. Samples and FIFO Depth of Sequencers**

Sequencer	Number of Samples	Depth of FIFO
SS3	1	1
SS2	4	4
SS1	4	4
SS0	8	8

For a given sample sequence, each sample is defined by two 4-bit nibbles in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn**

nibbles select the input pin, while the **ADCSSCTL<sub>n</sub>** nibbles contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASEN<sub>n</sub>** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register, and should be configured before being enabled.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence is allowed. In the **ADCSSCTL<sub>n</sub>** register, the **IEn** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO<sub>n</sub>)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTAT<sub>n</sub>)** registers along with **FULL** and **EMPTY** status flags. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

## 12.2.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- Sequence prioritization
- Trigger configuration

Most of the ADC control logic runs at the ADC clock rate of 14-18 MHz. The internal ADC divider is configured automatically by hardware when the system **XTAL** is selected. The automatic clock divider configuration targets 16.667 MHz operation for all Stellaris devices.

### 12.2.2.1 Interrupts

The register configurations of the sample sequencers dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the **MASK** bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals, and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding **IN** bit in **ADCISC**.

### 12.2.2.2 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

### 12.2.2.3 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. The external peripheral triggering sources vary by Stellaris family member, but all devices share the "Controller" and "Always" triggers. Software can initiate sampling by setting the **SS<sub>x</sub>** bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the "Always" trigger. If a sequence's priority is too high, it is possible to starve other lower priority sequences.

### 12.2.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 487). There is a single averaging circuit and all input channels receive the same amount of averaging whether they are single-ended or differential.

### 12.2.4 Analog-to-Digital Converter

The converter itself generates a 10-bit output value for selected analog input. Special analog pads are used to minimize the distortion on the input. An internal 3 V reference is used by the converter resulting in sample values ranging from 0x000 at 0 V input to 0x3FF at 3 V input when in single-ended input mode.

### 12.2.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the **D<sub>n</sub>** bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, its corresponding value in the **ADCSSMUXn** register must be set to one of the four differential pairs, numbered 0-3. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 12-2 on page 468). The ADC does not support other differential pairings such as analog input 0 with analog input 3. The number of differential pairs supported is dependent on the number of analog inputs (see Table 12-2 on page 468).

**Table 12-2. Differential Sampling Pairs**

Differential Pair	Analog Inputs
0	0 and 1
1	2 and 3
2	4 and 5
3	6 and 7

The voltage sampled in differential mode is the difference between the odd and even channels:

$\Delta V$  (differential voltage) =  $V_{IN\_EVEN}$  (even channels) –  $V_{IN\_ODD}$  (odd channels), therefore:

- If  $\Delta V = 0$ , then the conversion result = 0x1FF

- If  $\Delta V > 0$ , then the conversion result  $> 0x1FF$  (range is 0x1FF–0x3FF)
- If  $\Delta V < 0$ , then the conversion result  $< 0x1FF$  (range is 0–0x1FF)

The differential pairs assign polarities to the analog inputs: the even-numbered input is always positive, and the odd-numbered input is always negative. In order for a valid conversion result to appear, the negative input must be in the range of  $\pm 1.5$  V of the positive input. If an analog input is greater than 3 V or less than 0 V (the valid range for analog inputs), the input voltage is clipped, meaning it appears as either 3 V or 0 V, respectively, to the ADC.

Figure 12-2 on page 469 shows an example of the negative input centered at 1.5 V. In this configuration, the differential range spans from -1.5 V to 1.5 V. Figure 12-3 on page 470 shows an example where the negative input is centered at -0.75 V, meaning inputs on the positive input saturate past a differential voltage of -0.75 V since the input voltage is less than 0 V. Figure 12-4 on page 470 shows an example of the negative input centered at 2.25 V, where inputs on the positive channel saturate past a differential voltage of 0.75 V since the input voltage would be greater than 3 V.

**Figure 12-2. Differential Sampling Range,  $V_{IN\_ODD} = 1.5$  V**

**Figure 12-3. Differential Sampling Range,  $V_{IN\_ODD} = 0.75\text{ V}$** **Figure 12-4. Differential Sampling Range,  $V_{IN\_ODD} = 2.25\text{ V}$** 

### 12.2.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation, and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, since it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC.

The internal temperature sensor provides an analog temperature reading as well as a reference voltage. The voltage at the output terminal SENSO is given by the following equation:

$$SENSO = 2.7 - ((T + 55) / 75)$$

This relation is shown in Figure 12-5 on page 471.

**Figure 12-5. Internal Temperature Sensor Characteristic**

## 12.3 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and using a supported crystal frequency (see the **RCC** register). Using unsupported frequencies can cause faulty operation in the ADC module.

### 12.3.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps. The main steps include enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock by writing a value of 0x0001.0000 to the **RCGC0** register (see page 222).
2. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 393) in the associated GPIO block.
3. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority, and Sample Sequencer 3 as the lowest priority.

### 12.3.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization since each sample sequence is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by writing a 0 to the corresponding `ASENn` bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUX<sub>n</sub>** register.
4. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTL<sub>n</sub>** register. When programming the last nibble, ensure that the `END` bit is set. Failure to set the `END` bit causes unpredictable behavior.
5. If interrupts are to be used, write a 1 to the corresponding `MASK` bit in the **ADCIM** register.
6. Enable the sample sequencer logic by writing a 1 to the corresponding `ASENn` bit in the **ADCACTSS** register.

## 12.4 Register Map

Table 12-3 on page 472 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to the ADC base address of 0x4003.8000.

Note that the ADC module clock must be enabled before the registers can be programmed (see page 222). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 12-3. ADC Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	ADCACTSS	R/W	0x0000.0000	ADC Active Sample Sequencer	474
0x004	ADCRIS	RO	0x0000.0000	ADC Raw Interrupt Status	475
0x008	ADCIM	R/W	0x0000.0000	ADC Interrupt Mask	476

## 12.5 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

## Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

### ADC Active Sample Sequencer (ADCACTSS)

Base 0x4003.8000  
Offset 0x000  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ASEN3	R/W	0	ADC SS3 Enable Specifies whether Sample Sequencer 3 is enabled. If set, the sample sequence logic for Sequencer 3 is active. Otherwise, the sequencer is inactive.
2	ASEN2	R/W	0	ADC SS2 Enable Specifies whether Sample Sequencer 2 is enabled. If set, the sample sequence logic for Sequencer 2 is active. Otherwise, the sequencer is inactive.
1	ASEN1	R/W	0	ADC SS1 Enable Specifies whether Sample Sequencer 1 is enabled. If set, the sample sequence logic for Sequencer 1 is active. Otherwise, the sequencer is inactive.
0	ASEN0	R/W	0	ADC SS0 Enable Specifies whether Sample Sequencer 0 is enabled. If set, the sample sequence logic for Sequencer 0 is active. Otherwise, the sequencer is inactive.

## Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without having to generate controller interrupts.

### ADC Raw Interrupt Status (ADCRIS)

Base 0x4003.8000  
Offset 0x004  
Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INR3	RO	0	SS3 Raw Interrupt Status This bit is set by hardware when a sample with its respective <b>ADCSSCTL3 IE</b> bit has completed conversion. This bit is cleared by setting the <b>IN3</b> bit in the <b>ADCISC</b> register.
2	INR2	RO	0	SS2 Raw Interrupt Status This bit is set by hardware when a sample with its respective <b>ADCSSCTL2 IE</b> bit has completed conversion. This bit is cleared by setting the <b>IN2</b> bit in the <b>ADCISC</b> register.
1	INR1	RO	0	SS1 Raw Interrupt Status This bit is set by hardware when a sample with its respective <b>ADCSSCTL1 IE</b> bit has completed conversion. This bit is cleared by setting the <b>IN1</b> bit in the <b>ADCISC</b> register.
0	INR0	RO	0	SS0 Raw Interrupt Status This bit is set by hardware when a sample with its respective <b>ADCSSCTL0 IE</b> bit has completed conversion. This bit is cleared by setting the <b>IN30</b> bit in the <b>ADCISC</b> register.

## Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer raw interrupt signals are promoted to controller interrupts. Each raw interrupt signal can be masked independently.

### ADC Interrupt Mask (ADCIM)

Base 0x4003.8000  
Offset 0x008  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MASK3	R/W	0	SS3 Interrupt Mask When set, this bit allows the raw interrupt signal from Sample Sequencer 3 ( <b>ADCRIS</b> register <b>INR3</b> bit) to be promoted to a controller interrupt. When clear, the status of Sample Sequencer 3 does not affect the SS3 interrupt status.
2	MASK2	R/W	0	SS2 Interrupt Mask When set, this bit allows the raw interrupt signal from Sample Sequencer 2 ( <b>ADCRIS</b> register <b>INR2</b> bit) to be promoted to a controller interrupt. When clear, the status of Sample Sequencer 2 does not affect the SS2 interrupt status.
1	MASK1	R/W	0	SS1 Interrupt Mask When set, this bit allows the raw interrupt signal from Sample Sequencer 1 ( <b>ADCRIS</b> register <b>INR1</b> bit) to be promoted to a controller interrupt. When clear, the status of Sample Sequencer 1 does not affect the SS1 interrupt status.
0	MASK0	R/W	0	SS0 Interrupt Mask When set, this bit allows the raw interrupt signal from Sample Sequencer 0 ( <b>ADCRIS</b> register <b>INR0</b> bit) to be promoted to a controller interrupt. When clear, the status of Sample Sequencer 0 does not affect the SS0 interrupt status.

## Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequence interrupt conditions and shows the status of controller interrupts generated by the sample sequencers. When read, each bit field is the logical AND of the respective `INR` and `MASK` bits. Sample sequence nterrupts are cleared by setting the corresponding bit position. If software is polling the `ADCRIS` instead of generating interrupts, the sample sequence `INR` bits are still cleared via the `ADCISC` register, even if the `IN` bit is not set.

### ADC Interrupt Status and Clear (ADCISC)

Base 0x4003.8000

Offset 0x00C

Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IN3	R/W1C	0	<p><b>SS3 Interrupt Status and Clear</b>            This bit is set when both the <code>INR3</code> bit in the <code>ADCRIS</code> register and the <code>MASK3</code> bit in the <code>ADCIM</code> register are set, providing a level-based interrupt to the controller.            This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR3</code> bit.</p>
2	IN2	R/W1C	0	<p><b>SS2 Interrupt Status and Clear</b>            This bit is set when both the <code>INR2</code> bit in the <code>ADCRIS</code> register and the <code>MASK2</code> bit in the <code>ADCIM</code> register are set, providing a level-based interrupt to the controller.            This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR2</code> bit.</p>
1	IN1	R/W1C	0	<p><b>SS1 Interrupt Status and Clear</b>            This bit is set when both the <code>INR1</code> bit in the <code>ADCRIS</code> register and the <code>MASK1</code> bit in the <code>ADCIM</code> register are set, providing a level-based interrupt to the controller.            This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR1</code> bit.</p>
0	IN0	R/W1C	0	<p><b>SS0 Interrupt Status and Clear</b>            This bit is set when both the <code>INR0</code> bit in the <code>ADCRIS</code> register and the <code>MASK0</code> bit in the <code>ADCIM</code> register are set, providing a level-based interrupt to the controller.            This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR0</code> bit.</p>

## Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010

This register indicates overflow conditions in the sample sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

### ADC Overflow Status (ADCOSTAT)

Base 0x4003.8000  
Offset 0x010  
Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	OV3	R/W1C	0	SS3 FIFO Overflow When set, this bit specifies that the FIFO for Sample Sequencer 3 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped. This bit is cleared by writing a 1.
2	OV2	R/W1C	0	SS2 FIFO Overflow When set, this bit specifies that the FIFO for Sample Sequencer 2 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped. This bit is cleared by writing a 1.
1	OV1	R/W1C	0	SS1 FIFO Overflow When set, this bit specifies that the FIFO for Sample Sequencer 1 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped. This bit is cleared by writing a 1.
0	OV0	R/W1C	0	SS0 FIFO Overflow When set, this bit specifies that the FIFO for Sample Sequencer 0 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped. This bit is cleared by writing a 1.

## Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014

The **ADCEMUX** selects the event (trigger) that initiates sampling for each sample sequencer. Each sample sequencer can be configured with a unique trigger source.

### ADC Event Multiplexer Select (ADCEMUX)

Base 0x4003.8000  
Offset 0x014  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:12	EM3	R/W	0x0	SS3 Trigger Select This field selects the trigger source for Sample Sequencer 3. The valid configurations for this field are:
				Value      Event
				0x0      Controller (default)
				0x1      Analog Comparator 0
				0x2      Analog Comparator 1
				0x3      Reserved
				0x4      External (GPIO PB4)
				0x5      Timer In addition, the trigger must be enabled with the TNOTE bit in the <b>GPTMCTL</b> register (see page 424).
				0x6      PWM0 The PWM module 0 trigger can be configured with the <b>PWM0 Interrupt and Trigger Enable (PWM0INTEN)</b> register, see page 752.
				0x7      PWM1 The PWM module 1 trigger can be configured with the <b>PWM1INTEN</b> register, see page 752.
				0x8      PWM2 The PWM module 2 trigger can be configured with the <b>PWM2INTEN</b> register, see page 752.
				0x9-0xE reserved
				0xF      Always (continuously sample)

Bit/Field	Name	Type	Reset	Description
11:8	EM2	R/W	0x0	SS2 Trigger Select This field selects the trigger source for Sample Sequencer 2. The valid configurations for this field are:
			Value	Event
			0x0	Controller (default)
			0x1	Analog Comparator 0
			0x2	Analog Comparator 1
			0x3	Reserved
			0x4	External (GPIO PB4)
			0x5	Timer In addition, the trigger must be enabled with the TNOTE bit in the <b>GPTMCTL</b> register (see page 424).
			0x6	PWM0 The PWM module 0 trigger can be configured with the <b>PWM0 Interrupt and Trigger Enable (PWM0INTEN)</b> register, see page 752.
			0x7	PWM1 The PWM module 1 trigger can be configured with the <b>PWM1INTEN</b> register, see page 752.
			0x8	PWM2 The PWM module 2 trigger can be configured with the <b>PWM2INTEN</b> register, see page 752.
			0x9-0xE	reserved
			0xF	Always (continuously sample)

Bit/Field	Name	Type	Reset	Description
7:4	EM1	R/W	0x0	SS1 Trigger Select This field selects the trigger source for Sample Sequencer 1. The valid configurations for this field are:
			Value	Event
			0x0	Controller (default)
			0x1	Analog Comparator 0
			0x2	Analog Comparator 1
			0x3	Reserved
			0x4	External (GPIO PB4)
			0x5	Timer In addition, the trigger must be enabled with the TNOTE bit in the <b>GPTMCTL</b> register (see page 424).
			0x6	PWM0 The PWM module 0 trigger can be configured with the <b>PWM0 Interrupt and Trigger Enable (PWM0INTEN)</b> register, see page 752.
			0x7	PWM1 The PWM module 1 trigger can be configured with the <b>PWM1INTEN</b> register, see page 752.
			0x8	PWM2 The PWM module 2 trigger can be configured with the <b>PWM2INTEN</b> register, see page 752.
			0x9-0xE	reserved
			0xF	Always (continuously sample)

Bit/Field	Name	Type	Reset	Description
3:0	EM0	R/W	0x0	SS0 Trigger Select This field selects the trigger source for Sample Sequencer 0. The valid configurations for this field are:
			Value	Event
			0x0	Controller (default)
			0x1	Analog Comparator 0
			0x2	Analog Comparator 1
			0x3	Reserved
			0x4	External (GPIO PB4)
			0x5	Timer In addition, the trigger must be enabled with the TNOTE bit in the <b>GPTMCTL</b> register (see page 424).

			0xF	Always (continuously sample)

## Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018

This register indicates underflow conditions in the sample sequencer FIFOs. The corresponding underflow condition is cleared by writing a 1 to the relevant bit position.

### ADC Underflow Status (ADCUSTAT)

Base 0x4003.8000  
Offset 0x018  
Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	UV3	R/W1C	0	<p>SS3 FIFO Underflow</p> <p>When set, this bit specifies that the FIFO for Sample Sequencer 3 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>
2	UV2	R/W1C	0	<p>SS2 FIFO Underflow</p> <p>When set, this bit specifies that the FIFO for Sample Sequencer 2 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>
1	UV1	R/W1C	0	<p>SS1 FIFO Underflow</p> <p>When set, this bit specifies that the FIFO for Sample Sequencer 1 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>
0	UV0	R/W1C	0	<p>SS0 FIFO Underflow</p> <p>When set, this bit specifies that the FIFO for Sample Sequencer 0 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>

## Register 8: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

### ADC Sample Sequencer Priority (ADCSSPRI)

Base 0x4003.8000  
Offset 0x020  
Type R/W, reset 0x0000.3210

Bit/Field	Name	Type	Reset	Description
31:14	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:12	SS3	R/W	0x3	SS3 Priority This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 3. A priority encoding of 0 is highest and 3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.
11:10	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	SS2	R/W	0x2	SS2 Priority This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 2. A priority encoding of 0 is highest and 3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.
7:6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:4	SS1	R/W	0x1	SS1 Priority This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 1. A priority encoding of 0 is highest and 3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.
3:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
1:0	SS0	R/W	0x0	SS0 Priority This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 0. A priority encoding of 0 is highest and 3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.

## Register 9: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

### ADC Processor Sample Sequence Initiate (ADCPSSI)

Base 0x4003.8000

Offset 0x028

Reset	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SS3	WO	-	SS3 Initiate When set, this bit triggers sampling on Sample Sequencer 3 if the sequencer is enabled in the <b>ADCACTSS</b> register. Only a write by software is valid; a read of this register returns no meaningful data.
2	SS2	WO	-	SS2 Initiate When set, this bit triggers sampling on Sample Sequencer 2 if the sequencer is enabled in the <b>ADCACTSS</b> register. Only a write by software is valid; a read of this register returns no meaningful data.
1	SS1	WO	-	SS1 Initiate When set, this bit triggers sampling on Sample Sequencer 1 if the sequencer is enabled in the <b>ADCACTSS</b> register. Only a write by software is valid; a read of this register returns no meaningful data.
0	SS0	WO	-	SS0 Initiate When set, this bit triggers sampling on Sample Sequencer 0 if the sequencer is enabled in the <b>ADCACTSS</b> register. Only a write by software is valid; a read of this register returns no meaningful data.

## Register 10: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{\text{AVG}}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG = 7 provides unpredictable results.

### ADC Sample Averaging Control (ADCSAC)

Base 0x4003.8000  
Offset 0x030  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	AVG	R/W	0x0	Hardware Averaging Control Specifies the amount of hardware averaging that will be applied to ADC samples. The AVG field can be any value between 0 and 6. Entering a value of 7 creates unpredictable results.

Value	Description
0x0	No hardware oversampling
0x1	2x hardware oversampling
0x2	4x hardware oversampling
0x3	8x hardware oversampling
0x4	16x hardware oversampling
0x5	32x hardware oversampling
0x6	64x hardware oversampling
0x7	Reserved

## Register 11: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. This register is 32 bits wide and contains information for eight possible samples.

### ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

Base 0x4003.8000  
Offset 0x040  
Type R/W, reset 0x0000.0000

30:28	MUX7	R/W	0x0	8th Sample Input Select The MUX7 field is used during the eighth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. The value set here indicates the corresponding pin, for example, a value of 1 indicates the input is ADC1.
27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
26:24	MUX6	R/W	0x0	7th Sample Input Select The MUX6 field is used during the seventh sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
23	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
22:20	MUX5	R/W	0x0	6th Sample Input Select The MUX5 field is used during the sixth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
19	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
18:16	MUX4	R/W	0x0	5th Sample Input Select The MUX4 field is used during the fifth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:12	MUX3	R/W	0x0	4th Sample Input Select The MUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
11	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:8	MUX2	R/W	0x0	3rd Sample Input Select The MUX72 field is used during the third sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:4	MUX1	R/W	0x0	2nd Sample Input Select The MUX1 field is used during the second sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	MUX0	R/W	0x0	1st Sample Input Select The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

## Register 12: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set at some point, whether it be after the first sample, last sample, or any sample in between. This register is 32-bits wide and contains information for eight possible samples.

### ADC Sample Sequence Control 0 (ADCSSCTL0)

Base 0x4003.8000  
Offset 0x044  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	TS7	IE7	END7	D7	TS6	IE6	END6	D6	TS5	IE5	END5	D5	TS4	IE4	END4	D4
Reset	R/W 0															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	TS3	IE3	END3	D3	TS2	IE2	END2	D2	TS1	IE1	END1	D1	TS0	IE0	END0	D0
Reset	R/W 0															

Bit/Field	Name	Type	Reset	Description
31	TS7	R/W	0	8th Sample Temp Sensor Select This bit is used during the eighth sample of the sample sequence and specifies the input source of the sample. When set, the temperature sensor is read. When clear, the input pin specified by the <b>ADCSSMUX</b> register is read.
30	IE7	R/W	0	8th Sample Interrupt Enable This bit is used during the eighth sample of the sample sequence and specifies whether the raw interrupt signal ( <code>INR0</code> bit) is asserted at the end of the sample's conversion. If the <code>MASK0</code> bit in the <b>ADCIM</b> register is set, the interrupt is promoted to a controller-level interrupt. When this bit is set, the raw interrupt is asserted. When this bit is clear, the raw interrupt is not asserted. It is legal to have multiple samples within a sequence generate interrupts.
29	END7	R/W	0	8th Sample is End of Sequence The <code>END7</code> bit indicates that this is the last sample of the sequence. It is possible to end the sequence on any sample position. Samples defined after the sample containing a set <code>END</code> are not requested for conversion even though the fields may be non-zero. It is required that software write the <code>END</code> bit somewhere within the sequence. (Sample Sequencer 3, which only has a single sample in the sequence, is hardwired to have the <code>END0</code> bit set.) Setting this bit indicates that this sample is the last in the sequence.
28	D7	R/W	0	8th Sample Diff Input Select The <code>D7</code> bit indicates that the analog input is to be differentially sampled. The corresponding <b>ADCSSMUXx</b> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1". The temperature sensor does not have a differential option. When set, the analog inputs are differentially sampled.
27	TS6	R/W	0	7th Sample Temp Sensor Select Same definition as <code>TS7</code> but used during the seventh sample.

Bit/Field	Name	Type	Reset	Description
26	IE6	R/W	0	7th Sample Interrupt Enable Same definition as IE7 but used during the seventh sample.
25	END6	R/W	0	7th Sample is End of Sequence Same definition as END7 but used during the seventh sample.

**Register 13: ADC Sample Sequence Result FIFO 0 (ADCSS FIFO0), offset 0x048****Register 14: ADC Sample Sequence Result FIFO 1 (ADCSS FIFO1), offset 0x068****Register 15: ADC Sample Sequence Result FIFO 2 (ADCSS FIFO2), offset 0x088****Register 16: ADC Sample Sequence Result FIFO 3 (ADCSS FIFO3), offset 0x0A8**

---

**Important:** Use caution when reading this register. Performing a read may change bit status.

---

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSS FIFO0** register is used for Sample Sequencer 0, **ADCSS FIFO1** for Sequencer 1, **ADCSS FIFO2** for Sequencer 2, and **ADCSS FIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

## ADC Sample Sequence Result FIFO 0 (ADCSS FIFO0)

Base 0x4003.8000

Offset 0x048

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 25: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register defines the analog input configuration for a sample executed with Sample Sequencer 3. This register is 4-bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 488 for detailed bit descriptions.

### ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3)

## Register 26: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4

This register contains the configuration information for a sample executed with Sample Sequencer 3. The `END` bit is always set since there is only one sample in this sequencer. This register is 4-bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 490 for detailed bit descriptions.

## 13 Universal Asynchronous Receivers/Transmitters (UARTs)

Each Stellaris® Universal Asynchronous Receiver/Transmitter (UART) has the following features:

- Two fully programmable 16C550-type UARTs with IrDA support
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable baud-rate generator allowing speeds up to 3.125 Mbps
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23 µs) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Dedicated Direct Memory Access (DMA) transmit and receive channels

## 13.1 Block Diagram

**Figure 13-1. UART Module Block Diagram**

## 13.2 Functional Description

Each Stellaris UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 520). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEN bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART peripheral also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

### 13.2.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit, and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 13-2 on page 502 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 13-2. UART Character Frame**

### 13.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divider allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 516) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 517). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$\text{BRD} = \text{BRDI} + \text{BRDF} = \text{UARTSysClk} / (16 * \text{Baud Rate})$$

where **UARTSysClk** is the system clock connected to the UART.

The 6-bit fractional number (that is to be loaded into the **DIVFRAC** bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD[DIVFRAC]} = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 16x the baud-rate (referred to as **Baud16**). This reference clock is divided by 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 518), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

### 13.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The **BUSY** bit in the **UART Flag (UARTFR)** register (see page 513) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The **BUSY** bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the UnRx is continuously 1) and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 (described in “Transmit/Receive Logic” on page 501).

The start bit is valid and recognized if UnRx is still low on the eighth cycle of Baud16, otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 (that is, one bit period later) according to the programmed length of the data characters. The parity bit is then checked if parity mode was enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if UnRx is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that word.

### 13.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream, and half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. The UART signal pins can be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW. This drives the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63  $\mu$ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCR** register. See page 515 for more information on IrDA low-power pulse-duration configuration.

Figure 13-3 on page 504 shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 13-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10 ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased, or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency, or receiver setup time.

If the application does not require the use of the **UnRx** signal, the GPIO pin that has the **UnRx** signal as an alternate function must be configured as the **UnRx** signal and pulled High.

### 13.2.5 FIFO Operation

The UART has two 16-entry FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 509). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the **FEN** bit in **UARTLCRH** (page 518).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 513) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits) and the **UARTRSR** register shows overrun status via the **OE** bit.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 522). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include 1/8, 1/4, 1/2, 3/4, and 7/8. For example, if the 1/4 option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the 1/2 mark.

### 13.2.6 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the **UARTIFLS** register is met)
- Receive (when condition defined in the RXIFLSEL bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 527).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 524) by setting the corresponding IM bit to 1. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 526).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by setting the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 528).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

### 13.2.7 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the LBE bit in the **UARTCTL** register (see page 520). In loopback mode, data transmitted on UnTx is received on the UnRx input.

### 13.2.8 DMA Operation

The UART provides an interface connected to the μDMA controller. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART will assert a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever there is any data in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the μDMA controller depending how the DMA channel is configured.

To enable DMA operation for the receive channel, the RXDMAE bit of the **DMA Control (UARTDMACTL)** register should be set. To enable DMA operation for the transmit channel, the TXDMAE bit of **UARTDMACTL** should be set. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the DMAERR bit of **UARTDMACR** is set, then

when a receive error occurs, the DMA receive requests will be automatically disabled. This error condition can be cleared by clearing the UART error interrupt.

If DMA is enabled, then the μDMA controller will trigger an interrupt when a transfer is complete. The interrupt will occur on the UART interrupt vector. Therefore, if interrupts are used for UART operation and DMA is enabled, the UART interrupt handler must be designed to handle the μDMA completion interrupt.

See “Micro Direct Memory Access (μDMA)” on page 298 for more details about programming the μDMA controller.

### 13.2.9 IrDA SIR block

The IrDA SIR block contains an IrDA serial IR (SIR) protocol encoder/decoder. When enabled, the SIR block uses the `UnTx` and `UnRx` pins for the SIR protocol, which should be connected to an IR transceiver.

The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception.

## 13.3 Initialization and Configuration

To use the UARTs, the peripheral clock must be enabled by setting the `UART0` or `UART1` bits in the `RCCG1` register.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), since the `UARTIBRD` and `UARTFBRD` registers must be written before the `UARTLCRH` register. Using the equation described in “Baud-Rate Generation” on page 502, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the `DIVINT` field of the `UARTIBRD` register (see page 516) should be set to 10. The value to be loaded into the `UARTFBRD` register (see page 517) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the `UARTEN` bit in the `UARTCTL` register.
2. Write the integer portion of the BRD to the `UARTIBRD` register.

3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Optionally, configure the uDMA channel (see “Micro Direct Memory Access (μDMA)” on page 298) and enable the DMA option(s) in the **UARTDMACTL** register.
6. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

## 13.4 Register Map

Table 13-1 on page 507 lists the UART registers. The offset listed is a hexadecimal increment to the register’s address, relative to that UART’s base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000

Note that the UART module clock must be enabled before the registers can be programmed (see page 228). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

**Note:** The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 520) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Table 13-1. UART Register Map**

## 13.5 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

## Register 1: UART Data (UARTDR), offset 0x000

**Important:** Use caution when reading this register. Performing a read may change bit status.

This register is the data register (the interface to the FIFOs).

When FIFOs are enabled, data written to this location is pushed onto the transmit FIFO. If FIFOs are disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If FIFOs are disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

### UART Data (UARTDR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	OE	RO	0	UART Overrun Error The OE values are defined as follows:  Value Description 0 There has been no data loss due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss.
10	BE	RO	0	UART Break Error This bit is set to 1 when a break condition is detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state) and the next valid start bit is received.
9	PE	RO	0	UART Parity Error This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register. In FIFO mode, this error is associated with the character at the top of the FIFO.

Bit/Field	Name	Type	Reset	Description
8	FE	RO	0	UART Framing Error This bit is set to 1 when the received character does not have a valid stop bit (a valid stop bit is 1).
7:0	DATA	R/W	0	Data Transmitted or Received When written, the data that is to be transmitted via the UART. When read, the data that was received by the UART.

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared to 0 on reset.

### Reads

#### UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x004

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	OE	RO	0	UART Overrun Error When this bit is set to 1, data is received and the FIFO is already full. This bit is cleared to 0 by a write to <b>UARTECR</b> . The FIFO contents remain valid since no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must now read the data in order to empty the FIFO.
2	BE	RO	0	UART Break Error This bit is set to 1 when a break condition is detected, indicating that the received data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). This bit is cleared to 0 by a write to <b>UARTECR</b> . In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.
1	PE	RO	0	UART Parity Error This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register. This bit is cleared to 0 by a write to <b>UARTECR</b> .

Bit/Field	Name	Type	Reset	Description
0	FE	RO	0	<p>UART Framing Error</p> <p>This bit is set to 1 when the received character does not have a valid stop bit (a valid stop bit is 1).</p> <p>This bit is cleared to 0 by a write to <b>UARTECR</b>.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO.</p>

## Writes

If the FIFO is disabled (FEN is 0), this bit is set when the transmit holding register is empty. If the FIFO is enabled (FEN is 1), this bit is set when the transmit FIFO is empty.
6	RXFF	RO	0	UART Receive FIFO Full The meaning of this bit depends on the state of the FEN bit in the <b>UARTLCRH</b> register. If the FIFO is disabled, this bit is set when the receive holding register is full. If the FIFO is enabled, this bit is set when the receive FIFO is full.
5	TXFF	RO	0	UART Transmit FIFO Full The meaning of this bit depends on the state of the FEN bit in the <b>UARTLCRH</b> register. If the FIFO is disabled, this bit is set when the transmit holding register is full. If the FIFO is enabled, this bit is set when the transmit FIFO is full.
4	RXFE	RO	1	UART Receive FIFO Empty The meaning of this bit depends on the state of the FEN bit in the <b>UARTLCRH</b> register. If the FIFO is disabled, this bit is set when the receive holding register is empty. If the FIFO is enabled, this bit is set when the receive FIFO is empty.

Bit/Field	Name	Type	Reset	Description
3	BUSY	RO	0	<p>UART Busy</p> <p>When this bit is 1, the UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent from the shift register.</p> <p>This bit is set as soon as the transmit FIFO becomes non-empty (regardless of whether UART is enabled).</p>
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register is an 8-bit read/write register that stores the low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared to 0 when reset.

The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows:

$$\text{ILPDVSR} = \text{SysClk} / F_{\text{IrLPBaud16}}$$

where  $F_{\text{IrLPBaud16}}$  is nominally 1.8432 MHz.

You must choose the divisor so that  $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$ , which results in a low-power pulse duration of  $1.41\text{--}2.11 \mu\text{s}$  (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but that pulses greater than  $1.4 \mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated.

### UART IrDA Low-Power Register (UARTILPR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x020

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	ILPDVSR	R/W	0x00	IrDA Low-Power Divisor This is an 8-bit low-power divisor value.

## Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 502 for configuration details.

### UART Integer Baud-Rate Divisor (UARTIBRD)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x024

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DIVINT	R/W	0x0000	Integer Baud-Rate Divisor

## Register 6: UART Fractional Baud-Rate Divisor (UARTFBRD), offset 0x028

The **UARTFBRD** register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the **UARTFBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 502 for configuration details.

UART Fractional Baud-Rate Divisor (UARTFBRD)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x028

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	DIVFRAC	R/W	0x000	Fractional Baud-Rate Divisor

## Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

### UART Line Control (UARTLCRH)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x02C

Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	SPS	R/W	0	UART Stick Parity Select When bits 1, 2, and 7 of <b>UARTLCRH</b> are set, the parity bit is transmitted and checked as a 0. When bits 1 and 7 are set and 2 is cleared, the parity bit is transmitted and checked as a 1. When this bit is cleared, stick parity is disabled.
6:5	WLEN	R/W	0	UART Word Length The bits indicate the number of data bits transmitted or received in a frame as follows:  Value Description 0x3 8 bits 0x2 7 bits 0x1 6 bits 0x0 5 bits (default)
4	FEN	R/W	0	UART Enable FIFOs If this bit is set to 1, transmit and receive FIFO buffers are enabled (FIFO mode). When cleared to 0, FIFOs are disabled (Character mode). The FIFOs become 1-byte-deep holding registers.
3	STP2	R/W	0	UART Two Stop Bits Select If this bit is set to 1, two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received.

Bit/Field	Name	Type	Reset	Description
2	EPS	R/W	0	<p><b>UART Even Parity Select</b>            If this bit is set to 1, even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits.            When cleared to 0, then odd parity is performed, which checks for an odd number of 1s.            This bit has no effect when parity is disabled by the <code>PEN</code> bit.</p>
1	PEN	R/W	0	<p><b>UART Parity Enable</b>            If this bit is set to 1, parity checking and generation is enabled; otherwise, parity is disabled and no parity bit is added to the data frame.</p>
0	BRK	R/W	0	<p><b>UART Send Break</b>            If this bit is set to 1, a Low level is continually output on the <code>UnTX</code> output, after completing transmission of the current character. For the proper execution of the break command, the software must set this bit for at least two frames (character periods). For normal use, this bit must be cleared to 0.</p>

## Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set to 1.

To enable the UART module, the **UARTEN** bit must be set to 1. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by disabling bit 4 (FEN) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

### UART Control (UARTCTL)

UART0 base: 0x4000.C000

Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	RXE	R/W	1	UART Receive Enable If this bit is set to 1, the receive section of the UART is enabled. When the UART is disabled in the middle of a receive, it completes the current character before stopping.  <b>Note:</b> To enable reception, the <b>UARTEN</b> bit must also be set.
8	TXE	R/W	1	UART Transmit Enable If this bit is set to 1, the transmit section of the UART is enabled. When the UART is disabled in the middle of a transmission, it completes the current character before stopping.  <b>Note:</b> To enable transmission, the <b>UARTEN</b> bit must also be set.

Bit/Field	Name	Type	Reset	Description
7	LBE	R/W	0	UART Loop Back Enable If this bit is set to 1, the <code>UnTX</code> path is fed through the <code>UnRX</code> path.
6:3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	SIRLP	R/W	0	UART SIR Low Power Mode This bit selects the IrDA encoding mode. If this bit is cleared to 0, low-level bits are transmitted as an active High pulse with a width of 3/16th of the bit period. If this bit is set to 1, low-level bits are transmitted with a pulse width which is 3 times the period of the <code>IrLPBaud16</code> input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances. See page 515 for more information.
1	SIREN	R/W	0	UART SIR Enable If this bit is set to 1, the IrDA SIR block is enabled, and the UART will transmit and receive data using SIR protocol.
0	UARTEN	R/W	0	UART Enable If this bit is set to 1, the UART is enabled. When the UART is disabled in the middle of transmission or reception, it completes the current character before stopping.

## Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

### UART Interrupt FIFO Level Select (UARTIFLS)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x034

Type R/W, reset 0x0000.0012

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:3	RXIFLSEL	R/W	0x2	UART Receive Interrupt FIFO Level Select The trigger points for the receive interrupt are as follows:

Value	Description
0x0	RX FIFO $\geq \frac{1}{8}$ full
0x1	RX FIFO $\geq \frac{1}{4}$ full
0x2	RX FIFO $\geq \frac{1}{2}$ full (default)
0x3	RX FIFO $\geq \frac{3}{4}$ full
0x4	RX FIFO $\geq \frac{7}{8}$ full
0x5-0x7	Reserved

Bit/Field	Name	Type	Reset	Description
2:0	TXIFLSEL	R/W	0x2	UART Transmit Interrupt FIFO Level Select The trigger points for the transmit interrupt are as follows:
Value      Description				
0x0      TX FIFO $\leq \frac{1}{8}$ empty				
0x1      TX FIFO $\leq \frac{3}{4}$ empty				
0x2      TX FIFO $\leq \frac{1}{2}$ empty (default)				
0x3      TX FIFO $\leq \frac{1}{4}$ empty				
0x4      TX FIFO $\leq \frac{1}{8}$ empty				
0x5-0x7 Reserved				

## Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Writing a 1 to a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Writing a 0 prevents the raw interrupt signal from being sent to the interrupt controller.

### UART Interrupt Mask (UARTIM)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x038

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	OEIM	R/W	0	UART Overrun Error Interrupt Mask On a read, the current mask for the <b>OEIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>OEIM</b> interrupt to the interrupt controller.
9	BEIM	R/W	0	UART Break Error Interrupt Mask On a read, the current mask for the <b>BEIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>BEIM</b> interrupt to the interrupt controller.
8	PEIM	R/W	0	UART Parity Error Interrupt Mask On a read, the current mask for the <b>PEIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>PEIM</b> interrupt to the interrupt controller.
7	FEIM	R/W	0	UART Framing Error Interrupt Mask On a read, the current mask for the <b>FEIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>FEIM</b> interrupt to the interrupt controller.
6	RTIM	R/W	0	UART Receive Time-Out Interrupt Mask On a read, the current mask for the <b>RTIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>RTIM</b> interrupt to the interrupt controller.
5	TXIM	R/W	0	UART Transmit Interrupt Mask On a read, the current mask for the <b>TXIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>TXIM</b> interrupt to the interrupt controller.
4	RXIM	R/W	0	UART Receive Interrupt Mask On a read, the current mask for the <b>RXIM</b> interrupt is returned. Setting this bit to 1 promotes the <b>RXIM</b> interrupt to the interrupt controller.

Bit/Field	Name	Type	Reset	Description
3:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 11: UART Raw Interrupt Status (UARTRIS), offset 0x03C

The **UARTRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

### UART Raw Interrupt Status (UARTRIS)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x03C

Type RO, reset 0x0000.000F

7	FERIS	RO	0	UART Framing Error Raw Interrupt Status Gives the raw interrupt state (prior to masking) of this interrupt.
6	RTRIS	RO	0	UART Receive Time-Out Raw Interrupt Status Gives the raw interrupt state (prior to masking) of this interrupt.
5	TXRIS	RO	0	UART Transmit Raw Interrupt Status Gives the raw interrupt state (prior to masking) of this interrupt.
4	RXRIS	RO	0	UART Receive Raw Interrupt Status Gives the raw interrupt state (prior to masking) of this interrupt.
3:0	reserved	RO	0xF	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 12: UART Masked Interrupt Status (UARTMIS), offset 0x040

The **UARTMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

### UART Masked Interrupt Status (UARTMIS)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x040

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	OEMIS	RO	0	UART Overrun Error Masked Interrupt Status Gives the masked interrupt state of this interrupt.
9	BEMIS	RO	0	UART Break Error Masked Interrupt Status Gives the masked interrupt state of this interrupt.
8	PEMIS	RO	0	UART Parity Error Masked Interrupt Status Gives the masked interrupt state of this interrupt.
7	FEMIS	RO	0	UART Framing Error Masked Interrupt Status Gives the masked interrupt state of this interrupt.
6	RTMIS	RO	0	UART Receive Time-Out Masked Interrupt Status Gives the masked interrupt state of this interrupt.
5	TXMIS	RO	0	UART Transmit Masked Interrupt Status Gives the masked interrupt state of this interrupt.
4	RXMIS	RO	0	UART Receive Masked Interrupt Status Gives the masked interrupt state of this interrupt.
3:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 13: UART Interrupt Clear (UARTICR), offset 0x044

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

### UART Interrupt Clear (UARTICR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x044

Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

## 14 Synchronous Serial Interface (SSI)

The Stellaris® microcontroller includes two Synchronous Serial Interface (SSI) modules. Each SSI is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

Each Stellaris SSI module has the following features:

- Two SSI modules, each with the following features:
  - Master or slave operation
  - Support for Direct Memory Access (DMA)
  - Programmable clock bit rate and prescale
  - Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
  - Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
  - Programmable data frame size from 4 to 16 bits
  - Internal loopback test mode for diagnostic/debug testing

## 14.1 Block Diagram

Figure 14-1. SSI Module Block Diagram

## 14.2 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the DMA module. DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 570).

### 14.2.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (FSysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 564). The clock is further divided by a value from 1 to 256, which is  $1 + SCR$ , where  $SCR$  is the value programmed in the **SSI Control0 (SSICR0)** register (see page 557).

The frequency of the output clock SSIClk is defined by:

$$\text{SSIClk} = \text{FSysClk} / (\text{CPSDVSR} * (1 + SCR))$$

**Note:** For master mode, the system clock must be at least two times faster than the SSIClk. For slave mode, the system clock must be at least 12 times faster than the SSIClk.

See “Synchronous Serial Interface (SSI)” on page 821 to view SSI timing parameters.

### 14.2.2 FIFO Operation

#### 14.2.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 561), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the SSITx pin.

In slave mode, the SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the **SSI** bit in the **RGCG1** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The SSI can be configured to generate an interrupt or a µDMA request when the FIFO is empty.

#### 14.2.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the SSIRx pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

### 14.2.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service
- Receive FIFO service
- Receive FIFO time-out
- Receive FIFO overrun

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI can only generate a single interrupt request to the controller at any given time. You can mask each of the four individual maskable interrupts by setting the appropriate bits in the **SSI Interrupt Mask (SSIIM)** register (see page 565). Setting the appropriate mask bit to 1 enables the interrupt.

Provision of the individual outputs, as well as a combined interrupt output, allows use of either a global interrupt service routine, or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 567 and page 568, respectively).

#### 14.2.4 Frame Formats

Each data frame is between 4 and 16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. There are three basic frame types that can be selected:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock (**SSIClk**) is held inactive while the SSI is idle, and **SSIClk** transitions at the programmed frequency only during active transmission or reception of data. The idle state of **SSIClk** is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame (**SSIFss**) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the **SSIFss** pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of **SSIClk**, and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique, which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

##### 14.2.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 14-2 on page 547 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 14-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode, SSIClk and SSIFss are forced Low, and the transmit data line SSITx is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, SSIFss is pulsed High for one SSIClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSIClk, the MSB of the 4 to 16-bit data frame is shifted out on the SSITx pin. Likewise, the MSB of the received data is shifted onto the SSIRx pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each SSIClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSIClk after the LSB has been latched.

Figure 14-3 on page 547 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

**Figure 14-3. TI Synchronous Serial Frame Format (Continuous Transfer)**

#### 14.2.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSIFss signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the SSIClk signal are programmable through the SPO and SPH bits within the **SSISCR0** control register.

##### **SPO Clock Polarity Bit**

When the SPO clock polarity control bit is Low, it produces a steady state Low value on the SSIClk pin. If the SPO bit is High, a steady state High value is placed on the SSIClk pin when data is not being transferred.

**SPH Phase Control Bit**

The SPH phase control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is Low, data is captured on the first clock edge transition. If the SPH bit is High, data is captured on the second clock edge transition.

**14.2.4.3 Freescale SPI Frame Format with SPO=0 and SPH=0**

Single and continuous transmission signal sequences for Freescale SPI format with SPO=0 and SPH=0 are shown in Figure 14-4 on page 548 and Figure 14-5 on page 548.

**Figure 14-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

Note: Q is undefined.

**Figure 14-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. This causes slave data to be enabled onto the SSIRx input line of the master. The master SSITx output pad is enabled.

One half  $\text{SSIClk}$  period later, valid master data is transferred to the  $\text{SSITx}$  pin. Now that both the master and slave data have been set, the  $\text{SSIClk}$  master clock pin goes High after one further half  $\text{SSIClk}$  period.

The data is now captured on the rising and propagated on the falling edges of the  $\text{SSIClk}$  signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the  $\text{SSIFss}$  line is returned to its idle High state one  $\text{SSIClk}$  period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the  $\text{SSIFss}$  signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the  $\text{SPH}$  bit is logic zero. Therefore, the master device must raise the  $\text{SSIFss}$  pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the  $\text{SSIFss}$  pin is returned to its idle state one  $\text{SSIClk}$  period after the last bit has been captured.

#### 14.2.4.4 Freescale SPI Frame Format with $\text{SPO}=0$ and $\text{SPH}=1$

The transfer signal sequence for Freescale SPI format with  $\text{SPO}=0$  and  $\text{SPH}=1$  is shown in Figure 14-6 on page 549, which covers both single and continuous transfers.

**Figure 14-6. Freescale SPI Frame Format with  $\text{SPO}=0$  and  $\text{SPH}=1$**

**Note:** Q is undefined.

In this configuration, during idle periods:

- $\text{SSIClk}$  is forced Low
- $\text{SSIFss}$  is forced High
- The transmit data line  $\text{SSITx}$  is arbitrarily forced Low
- When the SSI is configured as a master, it enables the  $\text{SSIClk}$  pad
- When the SSI is configured as a slave, it disables the  $\text{SSIClk}$  pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the  $\text{SSIFss}$  master signal being driven Low. The master  $\text{SSITx}$  output is enabled. After a further one half  $\text{SSIClk}$  period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the  $\text{SSIClk}$  is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the  $\text{SSIClk}$  signal.

In the case of a single word transfer, after all bits have been transferred, the  $\text{SSIFss}$  line is returned to its idle High state one  $\text{SSIClk}$  period after the last bit has been captured.

For continuous back-to-back transfers, the SSIF<sub>ss</sub> pin is held Low between successive data words and termination is the same as that of the single word transfer.

#### 14.2.4.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 14-7 on page 550 and Figure 14-8 on page 550.

**Figure 14-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0**

Note: Q is undefined.

**Figure 14-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0**

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIF<sub>ss</sub> master signal being driven Low, which causes slave data to be immediately transferred onto the SSIRx line of the master. The master SSITx output pad is enabled.

One half period later, valid master data is transferred to the SSITx line. Now that both the master and slave data have been set, the SSIClk master clock pin becomes Low after one further half SSIClk period. This means that data is captured on the falling edges and propagated on the rising edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSIF<sub>ss</sub> line is returned to its idle High state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is logic zero. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

#### 14.2.4.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 14-9 on page 551, which covers both single and continuous transfers.

**Figure 14-9. Freescale SPI Frame Format with SPO=1 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. The master SSITx output pad is enabled. After a further one-half SSIClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSIClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSIClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSIFss pin remains in its active Low state, until the final bit of the last word has been captured, and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSIFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

#### 14.2.4.7 MICROWIRE Frame Format

Figure 14-10 on page 552 shows the MICROWIRE frame format, again for a single frame. Figure 14-11 on page 553 shows the same format when back-to-back frames are transmitted.

**Figure 14-10. MICROWIRE Frame Format (Single Frame)**

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSIFss causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the SSITx pin. SSIFss remains Low for the duration of the frame transmission. The SSIRx pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each SSIClk. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the SSIRx line on the falling edge of SSIClk. The SSI in turn latches each bit on the rising edge of SSIClk. At the end of the frame, for single transfers, the SSIFss signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, which causes the data to be transferred to the receive FIFO.

**Note:** The off-chip slave device can tristate the receive line either on the falling edge of SSIClk after the LSB has been latched by the receive shifter, or when the SSIFss pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSIFss line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of SSIClk, after the LSB of the frame has been latched into the SSI.

**Figure 14-11. MICROWIRE Frame Format (Continuous Transfer)**

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of SSIClk after SSIFss has gone Low. Masters that drive a free-running SSIClk must ensure that the SSIFss signal has sufficient setup and hold margins with respect to the rising edge of SSIClk.

Figure 14-12 on page 553 illustrates these setup and hold time requirements. With respect to the SSIClk rising edge on which the first bit of receive data is to be sampled by the SSI slave, SSIFss must have a setup of at least two times the period of SSIClk on which the SSI operates. With respect to the SSIClk rising edge previous to this edge, SSIFss must have a hold of at least one SSIClk period.

**Figure 14-12. MICROWIRE Frame Format, SSIFss Input Setup and Hold Requirements**

#### 14.2.5 DMA Operation

The SSI peripheral provides an interface connected to the μDMA controller. The DMA operation of the SSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When DMA operation is enabled, the SSI will assert a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever there is any data in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst DMA transfer requests are handled automatically by the μDMA controller depending how the DMA channel is configured. To enable DMA operation for the receive channel, the **RXDMAE** bit of the **DMA Control (SSIDMACTL)** register should be set. To enable DMA operation for the transmit channel, the **TXDMAE** bit of **SSIDMACTL** should be set. If DMA is enabled, then the μDMA controller will trigger an interrupt when a transfer is complete. The interrupt will occur on the SSI interrupt vector. Therefore, if interrupts are used for SSI operation and DMA is enabled, the SSI interrupt handler must be designed to handle the μDMA completion interrupt.

See “Micro Direct Memory Access (μDMA)” on page 298 for more details about programming the μDMA controller.

## 14.3 Initialization and Configuration

To use the SSI, its peripheral clock must be enabled by setting the **SSI** bit in the **RCGC1** register.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the **SSE** bit in the **SSICR1** register is disabled before making any configuration changes.
2. Select whether the SSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the clock prescale divisor by writing the **SSICPSR** register.
4. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (SCR)
  - Desired clock phase/polarity, if using Freescale SPI mode (**SPH** and **SPO**)
  - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (**FRF**)
  - The data size (**DSS**)
5. Optionally, configure the μDMA channel (see “Micro Direct Memory Access (μDMA)” on page 298) and enable the DMA option(s) in the **SSIDMACTL** register.
6. Enable the SSI by setting the **SSE** bit in the **SSICR1** register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (**SPO**=1, **SPH**=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned} FSSIClk &= FSysClk / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR})) \end{aligned}$$

In this case, if **CPSDVSR**=2, **SCR** must be 9.

The configuration sequence would be as follows:

1. Ensure that the **SSE** bit in the **SSICR1** register is disabled.

2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The SSI is then enabled by setting the **SSE** bit in the **SSICR1** register to 1.

## 14.4 Register Map

Table 14-1 on page 555 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

- SSI0: 0x4000.8000
- SSI1: 0x4000.9000

Note that the SSI module clock must be enabled before the registers can be programmed (see page 228). There must be a delay of 3 system clocks after the SSI module clock is enabled before any SSI module registers are accessed.

**Note:** The SSI must be disabled (see the **SSE** bit in the **SSICR1** register) before any of the control registers are reprogrammed.

**Table 14-1. SSI Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	SSICR0	R/W	0x0000.0000	SSI Control 0	557
0x004	SSICR1	R/W	0x0000.0000	SSI Control 1	559
0x008	SSIDR	R/W	0x0000.0000	SSI Data	561

## 14.5 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

## Register 1: SSI Control 0 (SSICR0), offset 0x000

**SSICR0** is control register 0 and contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

### SSI Control 0 (SSICR0)

SSI0 base: 0x4000.8000  
SSI1 base: 0x4000.9000  
Offset 0x000  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
SCR																
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description										
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
15:8	SCR	R/W	0x0000	<p>SSI Serial Clock Rate</p> <p>The value SCR is used to generate the transmit and receive bit rate of the SSI. The bit rate is:</p> $BR = F_{SSIC1k} / (CPSDVSR * (1 + SCR))$ <p>where CPSDVSR is an even value from 2-254 programmed in the <b>SSICPSR</b> register, and SCR is a value from 0-255.</p>										
7	SPH	R/W	0	<p>SSI Serial Clock Phase</p> <p>This bit is only applicable to the Freescale SPI Format.</p> <p>The SPH control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.</p> <p>When the SPH bit is 0, data is captured on the first clock edge transition. If SPH is 1, data is captured on the second clock edge transition.</p>										
6	SPO	R/W	0	<p>SSI Serial Clock Polarity</p> <p>This bit is only applicable to the Freescale SPI Format.</p> <p>When the SPO bit is 0, it produces a steady state Low value on the SSIClk pin. If SPO is 1, a steady state High value is placed on the SSIClk pin when data is not being transferred.</p>										
5:4	FRF	R/W	0x0	<p>SSI Frame Format Select</p> <p>The FRF values are defined as follows:</p> <table border="0"> <tr> <td>Value</td> <td>Frame Format</td> </tr> <tr> <td>0x0</td> <td>Freescale SPI Frame Format</td> </tr> <tr> <td>0x1</td> <td>Texas Instruments Synchronous Serial Frame Format</td> </tr> <tr> <td>0x2</td> <td>MICROWIRE Frame Format</td> </tr> <tr> <td>0x3</td> <td>Reserved</td> </tr> </table>	Value	Frame Format	0x0	Freescale SPI Frame Format	0x1	Texas Instruments Synchronous Serial Frame Format	0x2	MICROWIRE Frame Format	0x3	Reserved
Value	Frame Format													
0x0	Freescale SPI Frame Format													
0x1	Texas Instruments Synchronous Serial Frame Format													
0x2	MICROWIRE Frame Format													
0x3	Reserved													

Bit/Field	Name	Type	Reset	Description
3:0	DSS	R/W	0x00	SSI Data Size Select The DSS values are defined as follows:
				Value      Data Size
				0x0-0x2   Reserved
				0x3   4-bit data
				0x4   5-bit data
				0x5   6-bit data
				0x6   7-bit data
				0x7   8-bit data
				0x8   9-bit data
				0x9   10-bit data
				0xA   11-bit data
				0xB   12-bit data
				0xC   13-bit data
				0xD   14-bit data
				0xE   15-bit data
				0xF   16-bit data

## Register 2: SSI Control 1 (SSICR1), offset 0x004

**SSICR1** is control register 1 and contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

### SSI Control 1 (SSICR1)

SSI0 base: 0x4000.8000  
SSI1 base: 0x4000.9000  
Offset 0x004  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SOD	R/W	0	<p>SSI Slave Mode Output Disable</p> <p>This bit is relevant only in the Slave mode (<b>MS=1</b>). In multiple-slave systems, it is possible for the SSI master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto the serial output line. In such systems, the TXD lines from multiple slaves could be tied together. To operate in such a system, the <b>SOD</b> bit can be configured so that the SSI slave does not drive the <b>SSITx</b> pin.</p> <p>The <b>SOD</b> values are defined as follows:</p>

Value	Description
0	SSI can drive <b>SSITx</b> output in Slave Output mode.
1	SSI must not drive the <b>SSITx</b> output in Slave mode.

Bit/Field	Name	Type	Reset	Description
2	MS	R/W	0	<p>SSI Master/Slave Select</p> <p>This bit selects Master or Slave mode and can be modified only when SSI is disabled (<b>SSE=0</b>).</p> <p>The <b>MS</b> values are defined as follows:</p>

Value	Description
0	Device configured as a master.
1	Device configured as a slave.

Bit/Field	Name	Type	Reset	Description						
1	SSE	R/W	0	<p>SSI Synchronous Serial Port Enable Setting this bit enables SSI operation. The SSE values are defined as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>SSI operation disabled.</td></tr><tr><td>1</td><td>SSI operation enabled.</td></tr></tbody></table> <p><b>Note:</b> This bit must be set to 0 before any control registers are reprogrammed.</p>	Value	Description	0	SSI operation disabled.	1	SSI operation enabled.
Value	Description									
0	SSI operation disabled.									
1	SSI operation enabled.									
0	LBM	R/W	0	<p>SSI Loopback Mode Setting this bit enables Loopback Test mode. The LBM values are defined as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>Normal serial port operation enabled.</td></tr><tr><td>1</td><td>Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.</td></tr></tbody></table>	Value	Description	0	Normal serial port operation enabled.	1	Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.
Value	Description									
0	Normal serial port operation enabled.									
1	Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.									

## Register 3: SSI Data (SSIDR), offset 0x008

**Important:** Use caution when reading this register. Performing a read may change bit status.

**SSIDR** is the data register and is 16-bits wide. When **SSIDR** is read, the entry in the receive FIFO (pointed to by the current FIFO read pointer) is accessed. As data values are removed by the SSI receive logic from the incoming data frame, they are placed into the entry in the receive FIFO (pointed to by the current FIFO write pointer).

When **SSIDR** is written to, the entry in the transmit FIFO (pointed to by the write pointer) is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. It is loaded into the transmit serial shifter, then serially shifted out onto the **SSITx** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the **SSE** bit in the **SSICR1** register is set to zero. This allows the software to fill the transmit FIFO before enabling the SSI.

### SSI Data (SSIDR)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DATA	R/W	0x0000	SSI Receive/Transmit Data A read operation reads the receive FIFO. A write operation writes the transmit FIFO. Software must right-justify data when the SSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data.

**Register 4: SSI Status (SSISR), offset 0x00C**

**SSISR** is a status register that contains bits that indicate the FIFO fill status and the SSI busy status.

## SSI Status (SSISR)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x00C

Type RO, reset 0x0000.0003

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO

reserved																
Type	RO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

## Bit/Field      Name      Type      Reset      Description

31:5      reserved      RO      0x00      Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

4      BSY      RO      0      SSI Busy Bit

The **BSY** values are defined as follows:

## Value      Description

0      SSI is idle.

1      SSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.

3      RFF      RO      0      SSI Receive FIFO Full

The **RFF** values are defined as follows:

## Value      Description

0      Receive FIFO is not full.

1      Receive FIFO is full.

2      RNE      RO      0      SSI Receive FIFO Not Empty

The **RNE** values are defined as follows:

## Value      Description

0      Receive FIFO is empty.

1      Receive FIFO is not empty.

1      TNF      RO      1      SSI Transmit FIFO Not Full

The **TNF** values are defined as follows:

## Value      Description

0      Transmit FIFO is full.

1      Transmit FIFO is not full.

Bit/Field	Name	Type	Reset	Description
0	TFE	R0	1	SSI Transmit FIFO Empty The TFE values are defined as follows:
Value Description				
0    Transmit FIFO is not empty.				
1    Transmit FIFO is empty.				

## Register 5: SSI Clock Prescale (SSICPSR), offset 0x010

**SSICPSR** is the clock prescale register and specifies the division factor by which the system clock must be internally divided before further use.

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

### SSI Clock Prescale (SSICPSR)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x010

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
reserved																
Type	RO	R/W														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
CPSDVSR																

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CPSDVSR	R/W	0x00	SSI Clock Prescale Divisor This value must be an even number from 2 to 254, depending on the frequency of <b>SSIClk</b> . The LSB always returns 0 on reads.

## Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared to 0 on reset.

On a read, this register gives the current value of the mask on the relevant interrupt. A write of 1 to the particular bit sets the mask, enabling the interrupt to be read. A write of 0 clears the corresponding mask.

### SSI Interrupt Mask (SSIIM)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x014

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXIM	R/W	0	SSI Transmit FIFO Interrupt Mask The TXIM values are defined as follows:  Value Description 0 TX FIFO half-full or less condition interrupt is masked. 1 TX FIFO half-full or less condition interrupt is not masked.
2	RXIM	R/W	0	SSI Receive FIFO Interrupt Mask The RXIM values are defined as follows:  Value Description 0 RX FIFO half-full or more condition interrupt is masked. 1 RX FIFO half-full or more condition interrupt is not masked.
1	RTIM	R/W	0	SSI Receive Time-Out Interrupt Mask The RTIM values are defined as follows:  Value Description 0 RX FIFO time-out interrupt is masked. 1 RX FIFO time-out interrupt is not masked.

Bit/Field	Name	Type	Reset	Description
0	RORIM	R/W	0	SSI Receive Overrun Interrupt Mask The RORIM values are defined as follows:
Value Description				
0 RX FIFO overrun interrupt is masked.				
1 RX FIFO overrun interrupt is not masked.				

## Register 7: SSI Raw Interrupt Status (SSIRIS), offset 0x018

The **SSIRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

### SSI Raw Interrupt Status (SSIRIS)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x018

Type RO, reset 0x0000.0008

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXRIS	RO	1	SSI Transmit FIFO Raw Interrupt Status Indicates that the transmit FIFO is half full or less, when set.
2	RXRIS	RO	0	SSI Receive FIFO Raw Interrupt Status Indicates that the receive FIFO is half full or more, when set.
1	RTRIS	RO	0	SSI Receive Time-Out Raw Interrupt Status Indicates that the receive time-out has occurred, when set.
0	RORRIS	RO	0	SSI Receive Overrun Raw Interrupt Status Indicates that the receive FIFO has overflowed, when set.

## Register 8: SSI Masked Interrupt Status (SSIMIS), offset 0x01C

The **SSIMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

### SSI Masked Interrupt Status (SSIMIS)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x01C

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXMIS	RO	0	SSI Transmit FIFO Masked Interrupt Status Indicates that the transmit FIFO is half full or less, when set.
2	RXMIS	RO	0	SSI Receive FIFO Masked Interrupt Status Indicates that the receive FIFO is half full or more, when set.
1	RTMIS	RO	0	SSI Receive Time-Out Masked Interrupt Status Indicates that the receive time-out has occurred, when set.
0	RORMIS	RO	0	SSI Receive Overrun Masked Interrupt Status Indicates that the receive FIFO has overflowed, when set.

## Register 9: SSI Interrupt Clear (SSIICR), offset 0x020

The **SSIICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

### SSI Interrupt Clear (SSIICR)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x020

Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	RTIC	W1C	0	SSI Receive Time-Out Interrupt Clear The RTIC values are defined as follows:  Value Description 0 No effect on interrupt. 1 Clears interrupt.
0	RORIC	W1C	0	SSI Receive Overrun Interrupt Clear The RORIC values are defined as follows:  Value Description 0 No effect on interrupt. 1 Clears interrupt.

**Register 10: SSI DMA Control (SSIDMACTL), offset 0x024**

The **SSIDMACTL** register is the DMA control register.

## SSI DMA Control (SSIDMACTL)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x024

Type R/W, reset 0x0000.0000

## Bit/Field      Name      Type      Reset      Description

31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	TXDMAE	R/W	0	Transmit DMA Enable If this bit is set to 1, DMA for the transmit FIFO is enabled.
0	RXDMAE	R/W	0	Receive DMA Enable If this bit is set to 1, DMA for the receive FIFO is enabled.

## Register 11: SSI Peripheral Identification 4 (SSIPeriphID4), offset 0xFD0

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 4 (SSIPeriphID4)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFD0

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID4	RO	0x00	SSI Peripheral ID Register[7:0] Can be used by software to identify the presence of this peripheral.

## Register 12: SSI Peripheral Identification 5 (SSIPeriphID5), offset 0xFD4

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 5 (SSIPeriphID5)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFD4

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID5	RO	0x00	SSI Peripheral ID Register[15:8] Can be used by software to identify the presence of this peripheral.

## Register 13: SSI Peripheral Identification 6 (SSIPeriphID6), offset 0xFD8

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 6 (SSIPeriphID6)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFD8

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID6	RO	0x00	SSI Peripheral ID Register[23:16] Can be used by software to identify the presence of this peripheral.

#### **Register 14: SSI Peripheral Identification 7 (SSIPeriphID7), offset 0xFDC**

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

## SSI Peripheral Identification 7 (SSIPeriphID7)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFDC

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID7	RO	0x00	SSI Peripheral ID Register[31:24] Can be used by software to identify the presence of this peripheral.

## Register 15: SSI Peripheral Identification 0 (SSIPeriphID0), offset 0xFE0

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 0 (SSIPeriphID0)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFE0

Type RO, reset 0x0000.0022

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID0	RO	0x22	SSI Peripheral ID Register[7:0] Can be used by software to identify the presence of this peripheral.

### **Register 16: SSI Peripheral Identification 1 (SSIPeriphID1), offset 0xFE4**

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

## SSI Peripheral Identification 1 (SSIPeriphID1)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFE4

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID1	RO	0x00	SSI Peripheral ID Register [15:8] Can be used by software to identify the presence of this peripheral.

## Register 17: SSI Peripheral Identification 2 (SSIPeriphID2), offset 0xFE8

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 2 (SSIPeriphID2)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFE8

Type RO, reset 0x0000.0018

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID2	RO	0x18	SSI Peripheral ID Register [23:16] Can be used by software to identify the presence of this peripheral.

## Register 18: SSI Peripheral Identification 3 (SSIPeriphID3), offset 0xFEC

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 3 (SSIPeriphID3)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFEC

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID3	RO	0x01	SSI Peripheral ID Register [31:24] Can be used by software to identify the presence of this peripheral.

## Register 19: SSI PrimeCell Identification 0 (SSIPCellID0), offset 0xFF0

The **SSIPCellIDn** registers are hard-coded, and the fields within the register determine the reset value.

## SSI PrimeCell Identification 0 (SSIPCellID0)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFF0

Type RO, reset 0x0000.000D

7:0	CID1	RO	0xF0	SSI PrimeCell ID Register [15:8] Provides software a standard cross-peripheral identification system.

## Register 21: SSI PrimeCell Identification 2 (SSIPCellID2), offset 0xFF8

The **SSIPCellIDn** registers are hard-coded, and the fields within the register determine the reset value.

### SSI PrimeCell Identification 2 (SSIPCellID2)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFF8

Type RO, reset 0x0000.0005

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID2	RO	0x05	SSI PrimeCell ID Register [23:16] Provides software a standard cross-peripheral identification system.

## Register 22: SSI PrimeCell Identification 3 (SSIPCellID3), offset 0xFFC

The **SSIPCellIDn** registers are hard-coded, and the fields within the register determine the reset value.

### SSI PrimeCell Identification 3 (SSIPCellID3)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFFC

Type RO, reset 0x0000.00B1

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID3	RO	0xB1	SSI PrimeCell ID Register [31:24] Provides software a standard cross-peripheral identification system.

## 15 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM3S3748 microcontroller includes two I<sup>2</sup>C modules, providing the ability to interact (both send and receive) with other I<sup>2</sup>C devices on the bus.

The Stellaris® I<sup>2</sup>C interface has the following features:

- Two I<sup>2</sup>C modules, each with the following features:
  - Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
    - Supports both sending and receiving data as either a master or a slave
    - Supports simultaneous master and slave operation
  - Four I<sup>2</sup>C modes
    - Master transmit
    - Master receive
    - Slave transmit
    - Slave receive
  - Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
  - Master and slave interrupt generation
    - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
    - Slave generates interrupts when data has been sent or requested by a master
  - Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

## 15.1 Block Diagram

Figure 15-1.  $I^2C$  Block Diagram

## 15.2 Functional Description

Each  $I^2C$  module is comprised of both master and slave functions which are implemented as separate peripherals. For proper operation, the SDA and SCL pins must be connected to bi-directional open-drain pads. A typical  $I^2C$  bus configuration is shown in Figure 15-2 on page 584.

See “Inter-Integrated Circuit ( $I^2C$ ) Interface” on page 822 for  $I^2C$  timing diagrams.

Figure 15-2.  $I^2C$  Bus Configuration

### 15.2.1 $I^2C$ Bus Functional Overview

The  $I^2C$  bus uses only two signals: SDA and SCL, named  $I^2CSDA$  and  $I^2CSCL$  on Stellaris microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the  $I^2C$  bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 585) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

### 15.2.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 15-3 on page 585.

**Figure 15-3. START and STOP Conditions**

### 15.2.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 15-4 on page 585. After the START condition, a slave address is sent. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSC** register). A zero indicates a transmit operation (send), and a one indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master; however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/send formats are then possible within a single transfer.

**Figure 15-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 15-5 on page 585). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master will write (send) data to the selected slave, and a one in this position means that the master will receive data from the slave.

**Figure 15-5. R/S Bit in First Byte**

### 15.2.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 15-6 on page 586).

**Figure 15-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

#### 15.2.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data sent out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 585.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Since the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledgement on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

#### 15.2.1.5 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a '1' (High) on SDA while another master transmits a '0' (Low) will switch off its data output stage and retire until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

#### 15.2.2 Available Speed Modes

The I<sup>2</sup>C clock rate is determined by the parameters: CLK\_PRD, TIMER\_PRD, SCL\_LP, and SCL\_HP.

where:

CLK\_PRD is the system clock period

SCL\_LP is the low phase of SCL (fixed at 6)

SCL\_HP is the high phase of SCL (fixed at 4)

TIMER\_PRD is the programmed value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register (see page 604).

The I<sup>2</sup>C clock period is calculated as follows:

$$\text{SCL\_PERIOD} = 2 * (1 + \text{TIMER\_PRD}) * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{CLK\_PRD}$$

For example:

```
CLK_PRD = 50 ns
TIMER_PRD = 2
SCL_LP=6
SCL_HP=4
```

yields a SCL frequency of:

$$1/T = 333 \text{ KHz}$$

Table 15-1 on page 587 gives examples of timer period, system clock, and speed mode (Standard or Fast).

**Table 15-1. Examples of I<sup>2</sup>C Master Timer Period versus Speed Mode**

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
4 MHz	0x01	100 Kbps	-	-
6 MHz	0x02	100 Kbps	-	-
12.5 MHz	0x06	89 Kbps	0x01	312 Kbps
16.7 MHz	0x08	93 Kbps	0x02	278 Kbps
20 MHz	0x09	100 Kbps	0x02	333 Kbps
25 MHz	0x0C	96.2 Kbps	0x03	312 Kbps
33 MHz	0x10	97.1 Kbps	0x04	330 Kbps
40 MHz	0x13	100 Kbps	0x04	400 Kbps
50 MHz	0x18	100 Kbps	0x06	357 Kbps

### 15.2.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master arbitration lost
- Master transaction error
- Slave transaction received
- Slave transaction requested

There is a separate interrupt signal for the I<sup>2</sup>C master and I<sup>2</sup>C slave modules. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

#### 15.2.3.1 I<sup>2</sup>C Master Interrupts

The I<sup>2</sup>C master module generates an interrupt when a transaction completes (either transmit or receive), when arbitration is lost, or when an error occurs during a transaction. To enable the I<sup>2</sup>C master interrupt, software must set the IM bit in the **I<sup>2</sup>C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition is met, software must check the ERROR and ARBLST bits in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction and to ensure that arbitration has not been lost. An error condition is asserted if the last transaction wasn't acknowledged by the slave. If an error is not detected and the master has not lost arbitration,

the application can proceed with the transfer. The interrupt is cleared by writing a 1 to the **IC** bit in the **I<sup>2</sup>C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register.

### 15.2.3.2 I<sup>2</sup>C Slave Interrupts

The slave module can generate an interrupt when data has been received or requested. This interrupt is enabled by writing a 1 to the **DATAIM** bit in the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I<sup>2</sup>C Slave Data (I2CSDR)** register, by checking the **RREQ** and **TREQ** bits of the **I<sup>2</sup>C Slave Control/Status (I2CSCSR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the **FBR** bit is set along with the **RREQ** bit. The interrupt is cleared by writing a 1 to the **DATAIC** bit in the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

In addition, the slave module can generate an interrupt when a start and stop condition is detected. These interrupts are enabled by writing a 1 to the **STARTIM** and **STOPIM** bits of the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register and cleared by writing a 1 to the **STOPIC** and **STARTIC** bits of the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register.

### 15.2.4 Loopback Operation

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the **LPBK** bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

### 15.2.5 Command Sequence Flow Charts

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode.

#### 15.2.5.1 I<sup>2</sup>C Master Command Sequences

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

**Figure 15-7. Master Single SEND**

**Figure 15-8. Master Single RECEIVE**

**Figure 15-9. Master Burst SEND**

**Figure 15-10. Master Burst RECEIVE**

**Figure 15-11. Master Burst RECEIVE after Burst SEND**

**Figure 15-12. Master Burst SEND after Burst RECEIVE**

### 15.2.5.2 $I^2C$ Slave Command Sequences

Figure 15-13 on page 595 presents the command sequence available for the  $I^2C$  slave.

**Figure 15-13. Slave Command Sequence**

### 15.3 Initialization and Configuration

The following example shows how to configure the I<sup>2</sup>C module to send a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock by writing a value of 0x0000.1000 to the **RCGC1** register in the System Control module.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. Also, be sure to enable the same pins for Open Drain operation.
4. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0020.
5. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```

TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;
TPR = (20MHz / (2 * (6 + 4) * 100000)) - 1;
TPR = 9

```

Write the **I2CMTPR** register with the value of 0x0000.0009.

6. Specify the slave address of the master and that the next operation will be a Send by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
7. Place data (byte) to be sent in the data register by writing the **I2CMDR** register with the desired data.
8. Initiate a single byte send of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
9. Wait until the transmission completes by polling the **I2CMCS** register's **BUSBSY** bit until it has been cleared.

## 15.4 Register Map

Table 15-2 on page 596 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base addresses for the master and slave:

- I<sup>2</sup>C 0: 0x4002.0000
- I<sup>2</sup>C 1: 0x4002.1000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 228). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The hw\_i2c.h file in the StellarisWare® Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that StellarisWare uses an offset between 0x000 and 0x018 with the slave base address.

## 15.5 Register Descriptions (I<sup>2</sup>C Master)

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset. See also “Register Descriptions (I<sup>2</sup>C Slave)” on page 610.

## Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Send (Low).

### I2C Master Slave Address (I2CMSA)

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								SA							
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:1	SA	R/W	0	I <sup>2</sup> C Slave Address This field specifies bits A6 through A0 of the slave address.
0	R/S	R/W	0	Receive/Send The R/S bit specifies if the next operation is a Receive (High) or Send (Low).
Value Description				
0 Send.				
1 Receive.				

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses four control bits when written, and accesses seven status bits when read.

The status register consists of seven bits, which when read determine the state of the I<sup>2</sup>C bus controller.

The control register consists of four bits: the RUN, START, STOP, and ACK bits. The START bit causes the generation of the START, or REPEATED START condition.

The STOP bit determines if the cycle stops at the end of the data cycle, or continues on to a burst. To generate a single send cycle, the **I<sup>2</sup>C Master Slave Address (I2CMCSA)** register is written with the desired address, the R/S bit is set to 0, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit must be set normally to logic 1. This causes the I<sup>2</sup>C bus controller to send an acknowledge automatically after each byte. This bit must be reset when the I<sup>2</sup>C bus controller requires no further data to be sent from the slave transmitter.

### Reads

#### I2C Master Control/Status (I2CMCS)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x004

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															BUSBSY
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	BUSY
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	BUSBSY	RO	0	Bus Busy This bit specifies the state of the I <sup>2</sup> C bus. If set, the bus is busy; otherwise, the bus is idle. The bit changes based on the START and STOP conditions.
5	IDLE	RO	0	I <sup>2</sup> C Idle This bit specifies the I <sup>2</sup> C controller state. If set, the controller is idle; otherwise the controller is not idle.
4	ARBLST	RO	0	Arbitration Lost This bit specifies the result of bus arbitration. If set, the controller lost arbitration; otherwise, the controller won arbitration.

Bit/Field	Name	Type	Reset	Description
3	DATAACK	RO	0	Acknowledge Data This bit specifies the result of the last data operation. If set, the transmitted data was not acknowledged; otherwise, the data was acknowledged.
2	ADRACK	RO	0	Acknowledge Address This bit specifies the result of the last address operation. If set, the transmitted address was not acknowledged; otherwise, the address was acknowledged.
1	ERROR	RO	0	Error This bit specifies the result of the last bus operation. If set, an error occurred on the last operation; otherwise, no error was detected. The error can be from the slave address not being acknowledged or the transmit data not being acknowledged.
0	BUSY	RO	0	I <sup>2</sup> C Busy This bit specifies the state of the controller. If set, the controller is busy; otherwise, the controller is idle. When the BUSY bit is set, the other status bits are not valid.

## Writes

### I<sup>2</sup>C Master Control/Status (I2CMCS)

I<sup>2</sup>C 0 base: 0x4002.0000

I<sup>2</sup>C 1 base: 0x4002.1000

Offset 0x004

Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	WO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ACK	WO	0	Data Acknowledge Enable When set, causes received data byte to be acknowledged automatically by the master. See field decoding in Table 15-3 on page 601.
2	STOP	WO	0	Generate STOP When set, causes the generation of the STOP condition. See field decoding in Table 15-3 on page 601.
1	START	WO	0	Generate START When set, causes the generation of a START or repeated START condition. See field decoding in Table 15-3 on page 601.

Bit/Field	Name	Type	Reset	Description
0	RUN	WO	0	I <sup>2</sup> C Master Enable When set, allows the master to send or receive data. See field decoding in Table 15-3 on page 601.

**Table 15-3. Write Field Decoding for I2CMCS[3:0] Field (Sheet 1 of 3)**

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
		R/S	ACK	STOP	START	
Idle	0	X <sup>a</sup>	0	1	1	START condition followed by SEND (master goes to the Master Transmit state).
	0	X	1	1	1	START condition followed by a SEND and STOP condition (master remains in Idle state).
	1	0	0	1	1	START condition followed by RECEIVE operation with negative ACK (master goes to the Master Receive state).
	1	0	1	1	1	START condition followed by RECEIVE and STOP condition (master remains in Idle state).
	1	1	0	1	1	START condition followed by RECEIVE (master goes to the Master Receive state).
	1	1	1	1	1	Illegal.
All other combinations not listed are non-operations.						NOP.
Master Transmit	X	X	0	0	1	SEND operation (master remains in Master Transmit state).
	X	X	1	0	0	STOP condition (master goes to Idle state).
	X	X	1	0	1	SEND followed by STOP condition (master goes to Idle state).
	0	X	0	1	1	Repeated START condition followed by a SEND (master remains in Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by SEND and STOP condition (master goes to Idle state).
	1	0	0	1	1	Repeated START condition followed by a RECEIVE operation with a negative ACK (master goes to Master Receive state).
	1	0	1	1	1	Repeated START condition followed by a SEND and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master goes to Master Receive state).
	1	1	1	1	1	Illegal.
	All other combinations not listed are non-operations.					NOP.

**Table 15-3. Write Field Decoding for I2CMCS[3:0] Field (Sheet 1 of 3) (continued)**

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
		R/S	ACK	STOP	START	
Master Receive	X	0	0	0	1	RECEIVE operation with negative ACK (master remains in Master Receive state).
	X	X	1	0	0	STOP condition (master goes to Idle state). <sup>b</sup>
	X	0	1	0	1	RECEIVE followed by STOP condition (master goes to Idle state).
	X	1	0	0	1	RECEIVE operation (master remains in Master Receive state).
	X	1	1	0	1	Illegal.
	1	0	0	1	1	Repeated START condition followed by RECEIVE operation with a negative ACK (master remains in Master Receive state).
	1	0	1	1	1	Repeated START condition followed by RECEIVE and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master remains in Master Receive state).
	0	X	0	1	1	Repeated START condition followed by SEND (master goes to Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by SEND and STOP condition (master goes to Idle state).
All other combinations not listed are non-operations.					NOP.	

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

## Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** Use caution when reading this register. Performing a read may change bit status.

This register contains the data to be transmitted when in the Master Transmit state, and the data received when in the Master Receive state.

### I2C Master Data (I2CMDR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	R/W	0x00	Data Transferred Data transferred during transaction.

## Register 4: I<sup>2</sup>C Master Timer Period (I2CMTPR), offset 0x00C

This register specifies the period of the SCL clock.

**Caution – Take care not to set bit 7 when accessing this register as unpredictable behavior can occur.**

### I2C Master Timer Period (I2CMTPR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x00C

Type R/W, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	TPR	R/W	0x1	SCL Clock Period This field specifies the period of the SCL clock. $\text{SCL\_PRD} = 2 * (1 + \text{TPR}) * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{CLK\_PRD}$ where: SCL_PRD is the SCL line period (I <sup>2</sup> C clock). TPR is the Timer Period register value (range of 1 to 127). SCL_LP is the SCL Low period (fixed at 6). SCL_HP is the SCL High period (fixed at 4).

## Register 5: I<sup>2</sup>C Master Interrupt Mask (I2CMIMR), offset 0x010

This register controls whether a raw interrupt is promoted to a controller interrupt.

### I2C Master Interrupt Mask (I2CMIMR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x010

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IM	R/W	0	Interrupt Mask This bit controls whether a raw interrupt is promoted to a controller interrupt. If set, the interrupt is not masked and the interrupt is promoted; otherwise, the interrupt is masked.

## Register 6: I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS), offset 0x014

This register specifies whether an interrupt is pending.

### I2C Master Raw Interrupt Status (I2CMRIS)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x014

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	RIS	RO	0	Raw Interrupt Status This bit specifies the raw interrupt state (prior to masking) of the I <sup>2</sup> C master block. If set, an interrupt is pending; otherwise, an interrupt is not pending.

## Register 7: I<sup>2</sup>C Master Masked Interrupt Status (I2CMMIS), offset 0x018

This register specifies whether an interrupt was signaled.

### I2C Master Masked Interrupt Status (I2CMMIS)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x018

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MIS	RO	0	Masked Interrupt Status This bit specifies the raw interrupt state (after masking) of the I <sup>2</sup> C master block. If set, an interrupt was signaled; otherwise, an interrupt has not been generated since the bit was last cleared.

## Register 8: I<sup>2</sup>C Master Interrupt Clear (I2CMICR), offset 0x01C

This register clears the raw interrupt.

### I2C Master Interrupt Clear (I2CMICR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x01C

Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IC	WO	0	<p>Interrupt Clear</p> <p>This bit controls the clearing of the raw interrupt. A write of 1 clears the interrupt; otherwise, a write of 0 has no affect on the interrupt state. A read of this register returns no meaningful data.</p>

## Register 9: I<sup>2</sup>C Master Configuration (I2CMCR), offset 0x020

This register configures the mode (Master or Slave) and sets the interface for test mode loopback.

### I2C Master Configuration (I2CMCR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x020

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SFE	R/W	0	I <sup>2</sup> C Slave Function Enable This bit specifies whether the interface may operate in Slave mode. If set, Slave mode is enabled; otherwise, Slave mode is disabled.
4	MFE	R/W	0	I <sup>2</sup> C Master Function Enable This bit specifies whether the interface may operate in Master mode. If set, Master mode is enabled; otherwise, Master mode is disabled and the interface clock is disabled.
3:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	LPBK	R/W	0	I <sup>2</sup> C Loopback This bit specifies whether the interface is operating normally or in Loopback mode. If set, the device is put in a test mode loopback configuration; otherwise, the device operates normally.

## **15.6 Register Descriptions (I<sup>2</sup>C Slave)**

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset. See also “Register Descriptions (I<sup>2</sup>C Master)” on page 597.

## Register 10: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x800

This register consists of seven address bits that identify the Stellaris I<sup>2</sup>C device on the I<sup>2</sup>C bus.

### I2C Slave Own Address (I2CSOAR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

Offset 0x800

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	OAR	R/W	0x00	I <sup>2</sup> C Slave Own Address This field specifies bits A6 through A0 of the slave address.

## Register 11: I<sup>2</sup>C Slave Control/Status (I2CSCSR), offset 0x804

This register accesses one control bit when written, and three status bits when read.

The read-only Status register consists of three bits: the FBR, RREQ, and TREQ bits. The First Byte Received (FBR) bit is set only after the Stellaris device detects its own slave address and receives the first data byte from the I<sup>2</sup>C master. The Receive Request (RREQ) bit indicates that the Stellaris I<sup>2</sup>C device has received a data byte from an I<sup>2</sup>C master. Read one data byte from the **I<sup>2</sup>C Slave Data (I2CSDR)** register to clear the RREQ bit. The Transmit Request (TREQ) bit indicates that the Stellaris I<sup>2</sup>C device is addressed as a Slave Transmitter. Write one data byte into the **I<sup>2</sup>C Slave Data (I2CSDR)** register to clear the TREQ bit.

The write-only Control register consists of one bit: the DA bit. The DA bit enables and disables the Stellaris I<sup>2</sup>C slave operation.

## 16 Universal Serial Bus (USB) Controller

The Stellaris® USB controller operates as a full-speed or low-speed function controller during point-to-point or multipoint (hub) communications with USB functions. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. Eight endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus six endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing. μDMA access to the FIFO allows minimal interference from system software. The controller has the capability to access an external power regulator through a power enable pad output (USB0EPEN) and power fault detect pad input (USB0PFLT).

The Stellaris USB module has the following features:

- Standards-based
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation
- USB Device or Host mode
- Integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 8 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 3 configurable IN endpoints and 3 configurable OUT endpoints
- 2 KB dedicated endpoint memory
  - Direct memory access (DMA)
  - One endpoint may be defined for double-buffered 1023-byte isochronous packet size

## 16.1 Block Diagram

Figure 16-1. USB Module Block Diagram

## 16.2 Functional Description

**Note:** A 9.1-k $\Omega$  resistor should be connected between the `USB0RBIAS` and ground. The 9.1-k $\Omega$  resistor should have a 1% tolerance and should be located in close proximity to the `USB0RBIAS` pin. Power dissipation in the resistor is low, so a chip resistor of any geometry may be used.

The Stellaris USB controller provides the ability for the controller to choose between Host controller and Device controller functionality. The USB controller requires both A and B connectors in the system to provide Host or Device connectivity. If both connectors are present, the controller provides external signals to enable or disable power to the `USB0VBUS` pin on the USB connector when not in use. The controller can only be used in Host or Device mode and cannot be used in both modes simultaneously. However, the controller can be manually switched at run time if the system requires both Host and Device functionality.

**Note:** When USB is used in the system, the minimum system frequency is 20 MHz.

### 16.2.1 Operation as a Device

This section describes the Stellaris USB controller's actions when it is being used as a USB Device. Before the USB controller's operating mode is changed from Device to Host or Host to Device, software must reset the USB controller by setting the `USB0` bit in the **Software Reset Control 2 (SRCR2)** register (see page 246). IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of Start of Frame (SOF) are all described.

When in Device mode, IN transactions are controlled by an endpoint's transmit interface and use the transmit endpoint registers for the given endpoint. OUT transactions are handled with an endpoint's receive interface and use the receive endpoint registers for the given endpoint.

When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).

- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint for a USB Device. However, in most cases the USB Device should use the dedicated control endpoint on the USB controller's endpoint 0.

### 16.2.1.1 Endpoints

When operating as a Device, the USB controller provides two dedicated control endpoints (IN and OUT) and six configurable endpoints (3 IN and 3 OUT) that can be used for communications with a Host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface.

Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.

The remaining six endpoints can be configured as control, bulk, interrupt, or isochronous endpoints. They should be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

### 16.2.1.2 IN Transactions as a Device

When operating as a USB Device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the three configurable IN endpoints are determined by the **USB Transmit FIFO Start Address (USBTXFIFOADD)** register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the **USB Maximum Transmit Data Endpoint n (USBTXMAXPn)** register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

**Note:** The maximum packet size set for any endpoint must not exceed the FIFO size. The **USBTXMAXPn** register should not be written to while data is in the FIFO as unexpected results may occur.

#### *Single-Packet Buffering*

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the **USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)** register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the **USB Transmit Control and Status Endpoint n Low (USBTXCSR<sub>L</sub>n)** register must be set. If the AUTOSET bit in the **USB Transmit Control and Status Endpoint n High (USBTXCSR<sub>H</sub>n)** register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE

are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

#### **Double-Packet Buffering**

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the **USBTXCSRLn** register must be set. If the AUTOSET bit in the **USBTXCSRn** register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the **USBTXCSRLn** register at this point indicates how many packets may be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the **USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

### **16.2.1.3 OUT Transactions as a Device**

When in Device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the three configurable OUT endpoints are determined by the **USB Receive FIFO Start Address (USBRXFIFOADD)** register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the **USB Maximum Receive Data Endpoint n (USBRXMAXPn)** register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

**Note:** In all cases, the maximum packet size must not exceed the FIFO size.

#### **Single-Packet Buffering**

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the **USB Receive Control and Status Endpoint n Low (USBRXCSRLn)** register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the **USB Receive Control and Status Endpoint n High (USBRXCSRn)** register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

#### **Double-Packet Buffering**

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the **USBRXCSRLn** register is set

and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note:** The FULL bit in **USBRXCSR<sub>n</sub>** is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the **USBRXCSR<sub>n</sub>** register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EP<sub>n</sub> bit is set in the **USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

#### 16.2.1.4 Scheduling

The Device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The Stellaris USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the Device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

#### 16.2.1.5 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

##### **Stalled Control Transfer**

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the **USB Control and Status Endpoint 0 Low (USBCSRL0)** register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what should have been the last packet.
3. The Host sends more than **USBRXMAXP<sub>n</sub>** bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

### **Zero Length OUT Data Packets**

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the Device request has been transferred.

However, if the Host sends a zero-length OUT data packet before the entire length of Device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the **USBCSRL0** register.

### **Setting the Device Address**

When a Host is attempting to enumerate the USB Device, it requests that the Device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the **USB Device Functional Address (USBFADDR)** register. However, care should be taken when writing to **USBFADDR** to avoid changing the address before the transaction is complete. This register should only be set after the SET\_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the Device has left the STATUS phase. In the case of a SET\_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the Device has responded to the IN request, the **USBFADDR** register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note:** If the **USBFADDR** register is set to the new value as soon as the Device receives the OUT transaction with the SET\_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the Device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the Device.

#### **16.2.1.6 Device Mode SUSPEND**

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the **USB Interrupt Enable (USBIE)** register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the **USB Power (USBPOWER)** register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling.

To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state. The USB controller is not able to Hibernate because all the internal states are lost as a result.

#### **16.2.1.7 Start-of-Frame**

When the USB controller is operating in Device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the **USB Frame Value (USBFRAME)** register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the **USBFRAME** register is not updated. The

USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

#### 16.2.1.8 USB RESET

When the USB controller is in Device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the **USBFADDR** register.
- Clears the **USB Endpoint Index (USBEPIIDX)** register.
- Flushes all endpoint FIFOs.
- Clears all control/status registers.
- Enables all endpoint interrupts.
- Generates a RESET interrupt.

When the application software driving the USB controller receives a RESET interrupt, any open pipes are closed and the USB controller waits for bus enumeration to begin.

#### 16.2.1.9 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the **USBPOWER** register. When the SOFTCONN bit is set, the PHY is placed in its normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET.

When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

When the USB controller is acting as a self-powered Device, a GPIO input or analog comparator input must be connected to VBUS and configured to generate an interrupt when the VBUS level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

**Note:** The USB controller does not generate an interrupt when the Device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

### 16.2.2 Operation as a Host

When the Stellaris USB controller is operating in Host mode, it can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Before the USB controller's operating mode is changed from Host to Device or Device to Host, software must reset the USB controller by setting the USB0 bit in the **Software Reset Control 2 (SRCR2)** register (see page 246). Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or

full-speed device to be used with a USB 2.0 hub. Control, bulk, isochronous, and interrupt transactions are supported. This section describes the USB controller's actions when it is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in Device mode, the FIFOs for endpoints should take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint to communicate with a Device. However, in most cases the USB controller should use the dedicated control endpoint to communicate with a Device's endpoint 0.

#### 16.2.2.1 Endpoints

The endpoint registers are used to control the USB endpoint interfaces which communicate with Device(s) that are connected. The endpoints consist of a dedicated control IN endpoint, a dedicated control OUT endpoint, three configurable OUT endpoints, and three configurable IN endpoints.

The dedicated control interface can only be used for control transactions to endpoint 0 of Devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of Devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, interrupt, or isochronous Device endpoints.

These USB interfaces can be used to simultaneously schedule as many as three independent OUT and three independent IN transactions to any endpoints on any Device. The IN and OUT controls are paired in three sets of registers. However, they can be configured to communicate with different types of endpoints and different endpoints on Devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a Device's bulk OUT endpoint 1, while the IN portion is communicating with a Device's interrupt IN endpoint 2.

Before accessing any Device, whether for point-to-point communications or for communications via a hub, the relevant **USB Receive Functional Address Endpoint n (USBRXFUNCADDRn)** or **USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn)** registers must be set for each receive or transmit endpoint to record the address of the Device being accessed.

The USB controller also supports connections to Devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

#### 16.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in Device mode except that the transaction first must be initiated by setting the **REQPKT** bit in the **USBCSRL0** register, indicating to the transaction scheduler that there

is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target Device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the **USBCSRL0** register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the **USBRXCSR $n$**  register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in **USBRXCSR $n$**  causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. The AUTOCL and AUTORQ bits can be used with μDMA accesses to perform complete bulk transfers without main processor intervention. When the RXRDY bit is cleared, the controller sends an acknowledge to the Device. When there is a known number of packets to be transferred, the **USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNT $n$ )** register associated with the endpoint should be configured to the number of packets to be transferred. The USB controller decrements the value in the **USBRQPKTCOUNT $n$**  register following each request. When the **USBRQPKTCOUNT $n$**  value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, **USBRQPKTCOUNT $n$**  should be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the **USBRXMAXP $n$**  register) such as may occur at the end of a bulk transfer.

If the Device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target Device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the **USBCSRL0** register. If the target Device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target Device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the **USBCSRL0** register.

### 16.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in Device mode. The TXRDY bit in the **USBTXCSR $n$**  register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the **USBTXCSR $n$**  register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO. Furthermore, AUTOSET can be used with the μDMA controller to perform complete bulk transfers without software intervention.

If the target Device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target Device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the **USBTXCSR $n$**  register. If the target Device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target Device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the **USBTXCSR $n$**  register.

### 16.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a Device is not responding. Isochronous endpoints can be scheduled from every frame to every  $2^{16}$  frames, in powers of 2.

The USB controller maintains a frame counter. If the target Device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target Device is a low-speed device, a K state is transmitted on the bus to act as a *keep-alive* to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the **REQPKT** bit is set or a transmit endpoint for which the **TXRDY** bit and/or the **FIFONE** bit is set.

An isochronous or interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt or isochronous transaction occurs per endpoint every n frames, where n is the interval set via the **USB Host Transmit Interval Endpoint n (USBTXINTERVALn)** or **USB Host Receive Interval Endpoint n (USBRXINTERVALn)** register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target Device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target Device before the endpoint times out.

#### 16.2.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed Device is connected to the USB controller via a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding **USB Receive Hub Address Endpoint n (USBRXHUBADDRn)** and **USB Receive Hub Port Endpoint n (USBRXHUBPORTn)** or the **USB Transmit Hub Address Endpoint n (USBTXHUBADDRn)** and **USB Transmit Hub Port Endpoint n (USBTXHUBPORTn)** registers. In addition, the speed at which the Device operates (full or low) must be recorded in the **USB Type Endpoint 0 (USBTYPE0)** (endpoint 0), **USB Host Configure Transmit Type Endpoint n (USBTXTYPEn)**, or **USB Host Configure Receive Type Endpoint n (USBRXTYPEn)** registers for each endpoint that is accessed by the Device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB Devices. To maximize the number of Devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to Device functions must be made following the completion of any on-going transactions on the endpoints affected.

#### 16.2.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target Device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

#### 16.2.2.7 Host SUSPEND

If the **SUSPEND** bit in the **USBPOWER** register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20 ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

#### 16.2.2.8 USB RESET

If the RESET bit in the **USBPOWER** register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to ensure correct resetting of the target Device. After the CPU has cleared the bit, the USB Host controller starts its frame counter and transaction scheduler.

#### 16.2.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the **USB Device Control (USBDEVCTL)** register, enabling the USB controller to wait for a Device to be connected. When a Device is detected, a connect interrupt is generated. The speed of the Device that has been connected can be determined by reading the **USBDEVCTL** register where the FSDEV bit is set for a full-speed Device, and the LSDEV bit is set for a low-speed Device. The USB controller must generate a RESET to the Device, and then the USB Host controller can begin Device enumeration. If the Device is disconnected while a session is in progress, a disconnect interrupt is generated.

#### 16.2.3 DMA Operation

The USB peripheral provides an interface connected to the μDMA controller. The μDMA operation of the USB is enabled through the **USBTXCSR<sub>H</sub>n** and **USBRXCSR<sub>H</sub>n** registers, for the TX and RX channels respectively. When μDMA operation is enabled, the USB asserts a μDMA request on the enabled receive or transmit channel when the associated FIFO can transfer data. When either FIFO can transfer data, the burst request for that channel is asserted. The μDMA channel must be configured to operate in Basic mode, and the size of the μDMA transfer must be restricted to whole multiples of the size of the USB FIFO. Both read and write transfers of the USB FIFOs using μDMA must be configured in this manner. For example, if the USB endpoint is configured with a FIFO size of 64 bytes, the μDMA channel can be used to transfer 64 bytes to or from the endpoint FIFO. If the number of bytes to transfer is less than 64, then a programmed I/O method must be used to copy the data to or from the FIFO.

If the DMAMOD bit in the **USBTXCSR<sub>H</sub>n/USBRXCSR<sub>H</sub>n** register is clear, an interrupt is generated after every packet is transferred, but the μDMA continues transferring data. If the DMAMOD bit is set, an interrupt is generated only when the entire μDMA transfer is complete. The interrupt occurs on the USB interrupt vector. Therefore, if interrupts are used for USB operation and the μDMA is enabled, the USB interrupt handler must be designed to handle the μDMA completion interrupt.

Care must be taken when using the μDMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of the value off the MAXLOAD field in the **USBRXCSR<sub>H</sub>n** register. The RXRDY bit is cleared as follows.

**Table 16-1. Remainder (MAXLOAD/4)**

Value	Description
0	MAXLOAD = 64 bytes
1	MAXLOAD = 61 bytes
2	MAXLOAD = 62 bytes
3	MAXLOAD = 63 bytes

**Table 16-2. Actual Bytes Read**

Value	Description
0	MAXLOAD
1	MAXLOAD+3
2	MAXLOAD+2
3	MAXLOAD+1

**Table 16-3. Packet Sizes That Clear RXRDY**

Value	Description
0	MAXLOAD, MAXLOAD-1, MAXLOAD-2, MAXLOAD-3
1	MAXLOAD
2	MAXLOAD, MAXLOAD-1
3	MAXLOAD, MAXLOAD-1, MAXLOAD-2

To enable DMA operation for the endpoint receive channel, the `DMAEN` bit of the **USBRXCSR $n$**  register should be set. To enable DMA operation for the endpoint transmit channel, the `DMAEN` bit of the **USBTXCSR $n$**  register must be set.

See “Micro Direct Memory Access (μDMA)” on page 298 for more details about programming the μDMA controller.

## 16.3 Initialization and Configuration

To use the USB Controller, the peripheral clock must be enabled via the **RCGC2** register (see page 237). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module (see page 237). To find out which GPIO port to enable, refer to Table 21-3 on page 803.

The initial configuration in all cases requires that the processor enable the USB controller and USB controller’s physical layer interface (PHY) before setting any registers. The next step is to enable the USB PLL so that the correct clocking is provided to the PHY. To ensure that voltage is not supplied to the bus incorrectly, the external power control signal, `USB0EPEN`, should be negated on start up by configuring the `USB0EPEN` and `USB0PFLT` pins to be controlled by the USB controller and not exhibit their default GPIO behavior.

The USB controller provides a method to set the current operating mode of the USB controller. This register should be written with the desired default mode so that the controller can respond to external USB events.

### 16.3.1 Pin Configuration

When using the Device controller portion of the USB controller in a system that also provides Host functionality, the power to VBUS must be disabled to allow the external Host controller to supply power. Usually, the `USB0EPEN` signal is used to control the external regulator and should be negated to avoid having two devices driving the `USB0VBUS` power pin on the USB connector.

When the USB controller is acting as a Host, it is in control of two signals that are attached to an external voltage supply that provides power to VBUS. The Host controller uses the `USB0EPEN` signal to enable or disable power to the `USB0VBUS` pin on the USB connector. An input pin, `USB0PFLT`, provides feedback when there has been a power fault on VBUS. The `USB0PFLT` signal can be configured to either automatically negate the `USB0EPEN` signal to disable power, and/or it can generate an interrupt to the interrupt controller to allow software to handle the power fault condition.

The polarity and actions related to both `USB0EPEN` and `USB0PFLT` are fully configurable in the USB controller. The controller also provides interrupts on Device insertion and removal to allow the Host controller code to respond to these external events.

### 16.3.2 Endpoint Configuration

To start communication in Host or Device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a Device. In Device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. In Device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In Device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, interrupt or isochronous mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. Isochronous endpoints can have packets with up to 1023 bytes per packet. In either mode, the maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a Device, the USB Device controller's soft connect must be enabled when the Device is ready to start communications, indicating to the Host controller that the Device is ready to start the enumeration process. If operating as a Host controller, the Device soft connect must be disabled and power must be provided to VBUS via the `USB0EPEN` signal.

## 16.4 Register Map

Table 16-4 on page 631 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 237). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

**Table 16-4. Universal Serial Bus (USB) Controller Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	USBFADDR	R/W	0x00	USB Device Functional Address	636

## 16.5 Register Descriptions

The LM3S3748 USB controller has Host-or-Device capabilities as specified in the **USBO** bit field in the **DC6** register (see page 219).

**Device**

This icon indicates that the register is used in Device mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode.

**Host**

This icon indicates that the register is used in Host mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode. The USB controller is in Device mode upon reset, so the reset values shown for these registers apply to the Device mode definition.

## Register 1: USB Device Functional Address (USBFADDR), offset 0x000

### Device

**USBFADDR** is an 8-bit register that contains the 7-bit address of the Device part of the transaction.

When the USB controller is being used in Device mode (the **HOST** bit in the **USBDEVCTL** register is clear), this register must be written with the address received through a SET\_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

**Important:** See the section called “Setting the Device Address” on page 624 for special considerations when writing this register.

### USB Device Functional Address (USBFADDR)

Base 0x4005.0000

Offset 0x000

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	FUNCADDR	R/W	0x00	Function Address Function Address of Device as received through SET_ADDRESS.

## Register 2: USB Power (USBPOWER), offset 0x001

**Host**

**USBPOWER** is an 8-bit register used for controlling SUSPEND and RESUME signaling and some basic operational aspects of the USB controller.

**Device**

### Host Mode

#### USB Power (USBPOWER)

Base 0x4005.0000

Offset 0x001

Type R/W, reset 0x20

Bit/Field	Name	Type	Reset	Description
7:4	reserved	RO	0x2	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RESET	R/W	0	RESET Signaling
		Value	Description	
		1	Enables RESET signaling on the bus.	
		0	Ends RESET signaling on the bus.	
2	RESUME	R/W	0	RESUME Signaling
		Value	Description	
		1	Enables RESUME signaling when the Device is in SUSPEND mode.	
		0	Ends RESUME signaling on the bus.	
		This bit must be cleared by software 20 ms after being set.		
1	SUSPEND	R/W1S	0	SUSPEND Mode
		Value	Description	
		1	Enables SUSPEND mode.	
		0	No effect.	
0	PWRDNPHY	R/W	0	Power Down PHY
		Value	Description	
		1	Powers down the internal USB PHY.	
		0	No effect.	

**Device Mode****USB Power (USBPOWER)**

Base 0x4005.0000

Offset 0x001

Type R/W, reset 0x20

	7	6	5	4	3	2	1	0	
Type	R/W	R/W	RO	RO	RO	R/W	RO	R/W	PWRDNPHY
Reset	0	0	1	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
7	ISOUP	R/W	0	Isochronous Update  Value Description 1 The USB controller waits for an SOF token from the time the TXRDY bit is set in the <b>USBTXCSRLn</b> register before sending the packet. If an IN token is received before an SOF token, then a zero-length data packet is sent. 0 No effect.  <b>Note:</b> This bit is only valid for isochronous transfers.
6	SOFTCONN	R/W	0	Soft Connect/Disconnect  Value Description 1 The USB D+/D- lines are enabled. 0 The USB D+/D- lines are tri-stated.
5:4	reserved	RO	0x2	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RESET	RO	0	RESET Signaling  Value Description 1 RESET signaling is present on the bus. 0 RESET signaling is not present on the bus.
2	RESUME	R/W	0	RESUME Signaling  Value Description 1 Enables RESUME signaling when the Device is in SUSPEND mode. 0 Ends RESUME signaling on the bus.  This bit must be cleared by software 10 ms (a maximum of 15 ms) after being set.

Bit/Field	Name	Type	Reset	Description
1	SUSPEND	RO	0	SUSPEND Mode  Value Description 1 The USB controller is in SUSPEND mode. 0 This bit is cleared when software reads the interrupt register or sets the RESUME bit above.
0	PWRDNPHY	R/W	0	Power Down PHY  Value Description 1 Powers down the internal USB PHY. 0 No effect.

## Register 3: USB Transmit Interrupt Status (USBTXIS), offset 0x002

**Important:** Use caution when reading this register. Performing a read may change bit status.

**Host**

**USBTXIS** is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–3. The meaning of the EPn bits in this register are based on the mode of the device. The EP1, EP2 and EP3 bits always indicate that the USB controller is sending data; however, in Host mode, the bits refer to OUT endpoints; while in Device mode, the bits refer to IN endpoints. The EP0 bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt.

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

### USB Transmit Interrupt Status (USBTXIS)

Base 0x4005.0000  
Offset 0x002  
Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EP3	RO	0	TX Endpoint 3 Interrupt Value Description 0 No interrupt. 1 The Endpoint 3 transmit interrupt is asserted.
2	EP2	RO	0	TX Endpoint 2 Interrupt Same description as EP15.
1	EP1	RO	0	TX Endpoint 1 Interrupt Same description as EP15.
0	EP0	RO	0	TX and RX Endpoint 0 Interrupt Value Description 0 No interrupt. 1 The Endpoint 0 transmit and receive interrupt is asserted.

## Register 4: USB Receive Interrupt Status (USBRXIS), offset 0x004

**Important:** Use caution when reading this register. Performing a read may change bit status.

**Host**

**USBRXIS** is a 16-bit read-only register that indicates which of the interrupts for receive endpoints 1–3 are currently active.

**Device**

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

### USB Receive Interrupt Status (USBRXIS)

Base 0x4005.0000  
Offset 0x004  
Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EP3	RO	0	RX Endpoint 3 Interrupt
		Value	Description	
		0	No interrupt.	
		1	The Endpoint 3 receive interrupt is asserted.	
2	EP2	RO	0	RX Endpoint 2 Interrupt Same description as EP3.
1	EP1	RO	0	RX Endpoint 1 Interrupt Same description as EP3.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 5: USB Transmit Interrupt Enable (USBTXIE), offset 0x006

**Host**

**USBTXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBTXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBTXIS** register is set. When a bit is cleared, the interrupt in the **USBTXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, the bits corresponding to endpoint 0 and transmit endpoints 1-3 are set to 1, while the remaining bits are set to 0.

### USB Transmit Interrupt Enable (USBTXIE)

Bit/Field	Name	Type	Reset	Description
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EP3	R/W	1	TX Endpoint 3 Interrupt Enable
		Value	Description	
		1	An interrupt is sent to the interrupt controller when the EP3 bit in the <b>USBTXIS</b> register is set.	
		0	The EP3 transmit interrupt is suppressed and not sent to the interrupt controller.	
2	EP2	R/W	1	TX Endpoint 2 Interrupt Enable Same description as EP3.
1	EP1	R/W	1	TX Endpoint 1 Interrupt Enable Same description as EP3.
0	EP0	R/W	1	TX and RX Endpoint 0 Interrupt Enable
		Value	Description	
		1	An interrupt is sent to the interrupt controller when the EP0 bit in the <b>USBTXIS</b> register is set.	
		0	The EP0 transmit interrupt is suppressed and not sent to the interrupt controller.	

## Register 6: USB Receive Interrupt Enable (USBRXIE), offset 0x008

**Host**

**USBRXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBRXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBRXIS** register is set. When a bit is cleared, the interrupt in the **USBRXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, the bits corresponding to receive endpoints 1-3 are set to 1, while the remaining bits are set to 0.

## Register 9: USB Frame Value (USBFRAME), offset 0x00C

**Host**

**USBFRAME** is a 16-bit read-only register that holds the last received frame number.

**Device**

USB Frame Value (USBFRAME)

Base 0x4005.0000

Offset 0x00C

Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:0	FRAME	RO	0x00	Frame Number

## Register 10: USB Endpoint Index (USBEPIDX), offset 0x00E

### Host

Each endpoint's buffer can be accessed by configuring a FIFO size and starting address. The **USBEPIDX** 16-bit register is used with the **USBTXFIFOSZ**, **USBRXFIFOSZ**, **USBTXFIFOADD**, and **USBRXFIFOADD** registers.

### Device

#### USB Endpoint Index (USBEPIDX)

Base 0x4005.0000

Offset 0x00E

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	EPIDX	R/W	0x0	<p>Endpoint Index</p> <p>This bit field configures which endpoint is accessed when reading or writing to one of the USB controller's indexed registers. A value of 0x0 corresponds to Endpoint 0 and a value of 0x3 corresponds to Endpoint 3.</p>

## Register 11: USB Test Mode (USBTEST), offset 0x00F

**Host**

**USBTEST** is an 8-bit register that is primarily used to put the USB controller into one of the four test modes for operation described in the *USB 2.0 Specification*, in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

**Device**

**Note:** Only one of these bits should be set at any time.

### Host Mode

#### USB Test Mode (USBTEST)

Base 0x4005.0000  
Offset 0x00F  
Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	FORCEH	R/W	0	Force Host Mode
				Value Description
				1 Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.
				0 No effect.
				While in this mode, status of the bus connection may be read using the DEV bit of the <b>USBDEVCCTL</b> register. The operating speed is determined from the FORCEFS bit.
6	FIFOACC	R/W1S	0	FIFO Access
				Value Description
				1 Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO.
				0 No effect.
				This bit is cleared automatically.
5	FORCEFS	R/W	0	Force Full-Speed Mode
				Value Description
				1 Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
				0 The USB controller operates at Low Speed.

Bit/Field	Name	Type	Reset	Description
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Device Mode

### USB Test Mode (USBTEST)

Base 0x4005.0000

Offset 0x00F

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	FIFOACC	R/W1S	0	FIFO Access  Value Description 1 Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO. 0 No effect.  This bit is cleared automatically.
5	FORCEFS	R/W	0	Force Full-Speed Mode  Value Description 1 Forces the USB controller into Full-Speed mode upon receiving a USB RESET. 0 The USB controller operates at Low Speed.
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 12: USB FIFO Endpoint 0 (USBFIFO0), offset 0x020****Register 13: USB FIFO Endpoint 1 (USBFIFO1), offset 0x024****Register 14: USB FIFO Endpoint 2 (USBFIFO2), offset 0x028****Register 15: USB FIFO Endpoint 3 (USBFIFO3), offset 0x02C**

**Important:** Use caution when reading this register. Performing a read may change bit status.

**Host**

These 32-bit registers provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

**Device**

Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see the section called “Single-Packet Buffering” on page 622). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–3, the associated FIFO is completely flushed.

**USB FIFO Endpoint 0 (USBFIFO0)**

Base 0x4005.0000

## Bit/Field      Name      Type      Reset      Description

31:0

EPDATA

R/W

0x0000.0000

Endpoint Data

Writing to this register loads the data into the Transmit FIFO and reading unloads data from the Receive FIFO.

## Register 16: USB Device Control (USBDEVCTL), offset 0x060

**Host**

**USBDEVCTL** provides the status information for the current operating mode (Host or Device) of the USB controller. If the USB controller is in Host mode, this register also indicates if a full- or low-speed Device has been connected.

### USB Device Control (USBDEVCTL)

Base 0x4005.0000

Offset 0x060

Type RO, reset 0x80

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	FSDEV	RO	0	Full-Speed Device Detected
		Value	Description	
		0	A full-speed Device has not been detected on the port.	
		1	A full-speed Device has been detected on the port.	
5	LSDEV	RO	0	Low-Speed Device Detected
		Value	Description	
		0	A low-speed Device has not been detected on the port.	
		1	A low-speed Device has been detected on the port.	
4:3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	HOST	RO	0	Host Mode
		Value	Description	
		0	The USB controller is acting as a Device.	
		1	The USB controller is acting as a Host.	
		<b>Note:</b>	This value is only valid while a session is in progress.	
1:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 17: USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ), offset 0x062****Register 18: USB Receive Dynamic FIFO Sizing (USBRXFIFOSZ), offset 0x063****Host**

These 8-bit registers allow the selected TX/RX endpoint FIFOs to be dynamically sized. **USBEPIIDX** is used to configure each transmit endpoint's FIFO size.

**Device**

## USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)

Base 0x4005.0000

Offset 0x062

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	DPB	R/W	0	Double Packet Buffer Support  Value Description 0 Only single-packet buffering is supported. 1 Double-packet buffering is supported.
3:0	SIZE	R/W	0x0	Max Packet Size Maximum packet size to be allowed. If DPB = 0, the FIFO also is this size; if DPB = 1, the FIFO is twice this size.  Value Packet Size (Bytes) 0x0 8 0x1 16 0x2 32 0x3 64 0x4 128 0x5 256 0x6 512 0x7 1024 0x8 2048 0x9-0xF Reserved

**Register 19: USB Transmit FIFO Start Address (USBTXFIFOADD), offset 0x064****Register 20: USB Receive FIFO Start Address (USBRXFIFOADD), offset 0x066****Host**

**USBTXFIFOADD** and **USBRXFIFOADD** are 16-bit registers that control the start address of the selected transmit and receive endpoint FIFOs.

**Device**

USB Transmit FIFO Start Address (USBTXFIFOADD)

Base 0x4005.0000

Offset 0x064

Type R/W, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:9	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8:0	ADDR	R/W	0x00	Transmit/Receive Start Address Start address of the endpoint FIFO.

## Register 21: USB Connect Timing (USBCONTIM), offset 0x07A

**Host**

This 8-bit configuration register specifies connection delay.

**Device**

USB Connect Timing (USBCONTIM)

Base 0x4005.0000

Offset 0x07A

Type R/W, reset 0x5C

Bit/Field	Name	Type	Reset	Description
7:4	WTCON	R/W	0x5	Connect Wait This field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 µs.
3:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 22: USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF), offset 0x07D

### Host

This 8-bit configuration register specifies the minimum time gap allowed between the start of the last transaction and the EOF for full-speed transactions.

### Device

USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF)

Base 0x4005.0000

Offset 0x07D

Type R/W, reset 0x77

Bit/Field	Name	Type	Reset	Description
7:0	FSEOFG	R/W	0x77	<p>Full-Speed End-of-Frame Gap</p> <p>This field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 µs.</p>

## Register 23: USB Low-Speed Last Transaction to End of Frame Timing (USBLSEOF), offset 0x07E

**Host**

This 8-bit configuration register specifies the minimum time gap that is to be allowed between the start of the last transaction and the EOF for low-speed transactions.

**Device**

USB Low-Speed Last Transaction to End of Frame Timing (USBLSEOF)

Base 0x4005.0000

Offset 0x07E

Type R/W, reset 0x72

Bit/Field	Name	Type	Reset	Description
7:0	LSEOFG	R/W	0x72	<p>Low-Speed End-of-Frame Gap</p> <p>This field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 <math>\mu</math>s. The default corresponds to 121.6 <math>\mu</math>s.</p>

**Register 24: USB Transmit Functional Address Endpoint 0  
(USBTXFUNCADDR0), offset 0x080**

**Register 25: USB Transmit Functional Address Endpoint 1  
(USBTXFUNCADDR1), offset 0x088**

**Register 26: USB Transmit Functional Address Endpoint 2  
(USBTXFUNCADDR2), offset 0x090**

**Register 27: USB Transmit Functional Address Endpoint 3  
(USBTXFUNCADDR3), offset 0x098**

**Host**

**USBTXFUNCADDRn** is an 8-bit read/write register that records the address of the target function to be accessed through the associated endpoint (EPn). **USBTXFUNCADDRn** must be defined for each transmit endpoint that is used.

**Note:** **USBTXFUNCADDR0** is used for both receive and transmit for endpoint 0.

**USB Transmit Functional Address Endpoint 0 (USBTXFUNCADDR0)**

Base 0x4005.0000

Offset 0x080

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	ADDR	R/W	0x00	Device Address Specifies the USB bus address for the target Device.

**Register 28: USB Transmit Hub Address Endpoint 0 (USBTXHUBADDR0), offset 0x082**

**Register 29: USB Transmit Hub Address Endpoint 1 (USBTXHUBADDR1), offset 0x08A**

**Register 30: USB Transmit Hub Address Endpoint 2 (USBTXHUBADDR2), offset 0x092**

**Register 31: USB Transmit Hub Address Endpoint 3 (USBTXHUBADDR3), offset 0x09A**

**Host**

**USBTXHUBADDRn** is an 8-bit read/write register that, like **USBTXHUBPORTn**, only must be written when a USB Device is connected to transmit endpoint EP<sub>n</sub> via a USB 2.0 hub. This register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** **USBTXHUBADDR0** is used for both receive and transmit for endpoint 0.

USB Transmit Hub Address Endpoint 0 (USBTXHUBADDR0)

Base 0x4005.0000

Offset 0x082

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	MULTTRAN	R/W	0	Multiple Translators
				Value Description
			0	Clear to indicate that the hub has a single transaction translator.
			1	Set to indicate that the hub has multiple transaction translators.
6:0	ADDR	R/W	0x00	Hub Address This field specifies the USB bus address for the USB 2.0 hub.

**Register 32: USB Transmit Hub Port Endpoint 0 (USBTXHUBPORT0), offset 0x083**

**Register 33: USB Transmit Hub Port Endpoint 1 (USBTXHUBPORT1), offset 0x08B**

**Register 34: USB Transmit Hub Port Endpoint 2 (USBTXHUBPORT2), offset 0x093**

**Register 35: USB Transmit Hub Port Endpoint 3 (USBTXHUBPORT3), offset 0x09B**

**Host**

**USBTXHUBPORTn** is an 8-bit read/write register that, like **USBTXHUBADDRn**, only must be written when a full- or low-speed Device is connected to transmit endpoint EPn via a USB 2.0 hub. This register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** **USBTXHUBPORT0** is used for both receive and transmit for endpoint 0.

USB Transmit Hub Port Endpoint 0 (USBTXHUBPORT0)

Base 0x4005.0000

Offset 0x083

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	PORT	R/W	0x00	Hub Port This field specifies the USB hub port number.

**Register 36: USB Receive Functional Address Endpoint 1  
(USBRXFUNCADDR1), offset 0x08C**

**Register 37: USB Receive Functional Address Endpoint 2  
(USBRXFUNCADDR2), offset 0x094**

**Register 38: USB Receive Functional Address Endpoint 3  
(USBRXFUNCADDR3), offset 0x09C**

**Host**

**USBRXFUNCADDRn** is an 8-bit read/write register that records the address of the target function accessed through the associated endpoint (EPn). **USBRXFUNCADDRn** must be defined for each receive endpoint that is used.

**Note:** **USBTXFUNCADDR0** is used for both receive and transmit for endpoint 0.

USB Receive Functional Address Endpoint 1 (USBRXFUNCADDR1)

Base 0x4005.0000  
Offset 0x08C

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	ADDR	R/W	0x00	Device Address This field specifies the USB bus address for the target Device.

**Register 39: USB Receive Hub Address Endpoint 1 (USBRXHUBADDR1),  
offset 0x08E**

**Register 40: USB Receive Hub Address Endpoint 2 (USBRXHUBADDR2),  
offset 0x096**

**Register 41: USB Receive Hub Address Endpoint 3 (USBRXHUBADDR3),  
offset 0x09E**

**Host**

**USBRXHUBADDRn** is an 8-bit read/write register that, like **USBRXHUBPORTn**, only must be written when a full- or low-speed Device is connected to receive endpoint EPn via a USB 2.0 hub. This register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** **USBTXHUBADDR0** is used for both receive and transmit for endpoint 0.

**USB Receive Hub Address Endpoint 1 (USBRXHUBADDR1)**

Base 0x4005.0000  
Offset 0x08E  
Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	MULTTRAN	R/W	0	Multiple Translators  Value Description 0 Clear to indicate that the hub has a single transaction translator. 1 Set to indicate that the hub has multiple transaction translators.
6:0	ADDR	R/W	0x00	Hub Address This field specifies the USB bus address for the USB 2.0 hub.

**Register 42: USB Receive Hub Port Endpoint 1 (USBRXHUBPORT1), offset 0x08F**

**Register 43: USB Receive Hub Port Endpoint 2 (USBRXHUBPORT2), offset 0x097**

**Register 44: USB Receive Hub Port Endpoint 3 (USBRXHUBPORT3), offset 0x09F**

**Host**

**USBRXHUBPORTn** is an 8-bit read/write register that, like **USBRXHUBADDRn**, only must be written when a full- or low-speed Device is connected to receive endpoint EPn via a USB 2.0 hub. This register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** **USBTXHUBPORT0** is used for both receive and transmit for endpoint 0.

#### USB Receive Hub Port Endpoint 1 (USBRXHUBPORT1)

Base 0x4005.0000  
Offset 0x08F  
Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	PORT	R/W	0x00	Hub Port This field specifies the USB hub port number.

### Register 45: USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1), offset 0x110

### Register 46: USB Maximum Transmit Data Endpoint 2 (USBTXMAXP2), offset 0x120

### Register 47: USB Maximum Transmit Data Endpoint 3 (USBTXMAXP3), offset 0x130

**Host**

The **USBTXMAXPn** 16-bit register defines the maximum amount of data that can be transferred through the transmit endpoint in a single operation.

**Device**

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the FLUSH bit in **USBTXCSRLn**) after writing the new value to this register.

**Note:** **USBTXMAXPn** must be set to an even number of bytes for proper interrupt generation in μDMA Basic Mode.

#### USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1)

Base 0x4005.0000

Offset 0x110

Type R/W, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:11	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:0	MAXLOAD	R/W	0x000	Maximum Payload This field specifies the maximum payload in bytes per transaction.

## Register 48: USB Control and Status Endpoint 0 Low (USBCSRL0), offset 0x102

**Host**

**USBCSRL0** is an 8-bit register that provides control and status bits for endpoint 0.

**Device**

### Host Mode

				Value Description
				0 No effect.
				1 Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.

This bit is automatically cleared after the flush is performed.

**Important:** This bit should only be set when TXRDY/RXRDY is set.  
At other times, it may cause data to be corrupted.

## Register 50: USB Receive Byte Count Endpoint 0 (USBCOUNT0), offset 0x108

**Host**

**USBCOUNT0** is an 8-bit read-only register that indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXRDY bit is set.

**Device**

USB Receive Byte Count Endpoint 0 (USBCOUNT0)

Base 0x4005.0000

Offset 0x108

Type RO, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	COUNT	RO	0x00	FIFO Count COUNT is a read-only value that indicates the number of received data bytes in the endpoint 0 FIFO.

## Register 51: USB Type Endpoint 0 (USBTYPE0), offset 0x10A

**Host**

This is an 8-bit register that must be written with the operating speed of the targeted Device being communicated with using endpoint 0.

### USB Type Endpoint 0 (USBTYPE0)

Base 0x4005.0000

Offset 0x10A

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description								
7:6	SPEED	R/W	0x0	<p>Operating Speed</p> <p>This field specifies the operating speed of the target Device. If selected, the target is assumed to have the same connection speed as the USB controller.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0 - 0x1</td><td>Reserved</td></tr> <tr> <td>0x2</td><td>Full</td></tr> <tr> <td>0x3</td><td>Low</td></tr> </tbody> </table>	Value	Description	0x0 - 0x1	Reserved	0x2	Full	0x3	Low
Value	Description											
0x0 - 0x1	Reserved											
0x2	Full											
0x3	Low											
5:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.								

## Register 52: USB NAK Limit (USBNAKLMT), offset 0x10B

**Host**

**USBNAKLMT** is an 8-bit register that sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their **USBTXINTERVALn** and **USBRXINTERVALn** registers.)

The number of frames selected is  $2^{(m-1)}$  (where  $m$  is the value set in the register, with valid values of 2–16). If the Host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

**Note:** A value of 0 or 1 disables the NAK timeout function.

### USB NAK Limit (USBNAKLMT)

Base 0x4005.0000

Offset 0x10B

Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4:0	NAKLMT	R/W	0x0	EP0 NAK Limit This field specifies the number of frames after receiving a stream of NAK responses.

### Register 53: USB Transmit Control and Status Endpoint 1 Low (USBTXCSRL1), offset 0x112

### Register 54: USB Transmit Control and Status Endpoint 2 Low (USBTXCSRL2), offset 0x122

### Register 55: USB Transmit Control and Status Endpoint 3 Low (USBTXCSRL3), offset 0x132

**Host**

**USBTXCSRLn** is an 8-bit register that provides control and status bits for transfers through the currently selected transmit endpoint.

**Device**

## **Register 59: USB Maximum Receive Data Endpoint 1 (USBRXMAXP1), offset 0x114**

## Register 60: USB Maximum Receive Data Endpoint 2 (USBRXMAXP2), offset 0x124

## Register 61: USB Maximum Receive Data Endpoint 3 (USBRXMAXP3), offset 0x134

**Host** The **USBRXMAXPn** is a 16-bit register which defines the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

**Device** Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operations.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the receive endpoint, and must not exceed half the FIFO size if double-buffering is required.

**Note:** **USBRXMAXPn** must be set to an even number of bytes for proper interrupt generation in µDMA Basic mode.

**Host**

**USBTXINTERVALn** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The **USBTXINTERVALn** register value defines a number of frames, as follows:

Transfer Type	Speed	Valid values (m)	Interpretation
Interrupt	Low-Speed or Full-Speed	0x01 – 0xFF	The polling interval is $m$ frames.
Isochronous	Full-Speed	0x01 – 0x10	The polling interval is $2^{(m-1)}$ frames.
Bulk	Full-Speed	0x02 – 0x10	The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function.

(USBRQPKTCOUNT2), offset 0x308**

**Register 85: USB Request Packet Count in Block Transfer Endpoint 3  
(USBRQPKTCOUNT3), offset 0x30C**

**Host**

This 16-bit read/write register is used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint n. The USB controller uses the value recorded in this register to determine the number of requests to issue where the AUTORQ bit in the **USBRXCSRHN** register has been set. See “IN Transactions as a Host” on page 626.

**Note:** Multiple packets combined into a single bulk packet within the FIFO count as one packet.

**USB Request Packet Count in Block Transfer Endpoint 1 (USBRQPKTCOUNT1)**

Base 0x4005.0000

Offset 0x304

Type R/W, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:0	COUNT	R/W	0x0000	Block Transfer Packet Count Sets the number of packets of the size defined by the MAXLOAD bit field that are to be transferred in a block transfer.

**Note:** This is only used in Host mode when AUTORQ is set. The bit has no effect in Device mode or when AUTORQ is not set.

## Register 86: USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS), offset 0x340

### Host

**USBRXDPKTBUFDIS** is a 16-bit register that indicates which of the receive endpoints have disabled the double-packet buffer functionality (see the section called “Double-Packet Buffering” on page 622).

### Device

## Register 87: USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS), offset 0x342

**Host**

**USBTXDPKTBUFDIS** is a 16-bit register that indicates which of the transmit endpoints have disabled the double-packet buffer functionality (see the section called “Double-Packet Buffering” on page 622).

**Device**

USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS)

Base 0x4005.0000

Offset 0x342

## Register 88: USB External Power Control (USBEPC), offset 0x400

**Host**

This 32-bit register specifies the function of the two-pin external power interface (USB0EPEN and USB0PFLT). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary because the fault condition may require a response faster than one provided by firmware.

**Device**

## Register 89: USB External Power Control Raw Interrupt Status (USBEPCRIS), offset 0x404

**Host**

This 32-bit register specifies the unmasked interrupt status of the two-pin external power interface.

**Device**

### USB External Power Control Raw Interrupt Status (USBEPCRIS)

Base 0x4005.0000

Offset 0x404

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	PF	RO	0	USB Power Fault Interrupt Status

Value Description  
1 A Power Fault status has been detected.  
0 An interrupt has not occurred.

This bit is cleared by writing a 1 to the **PF** bit in the **USBEPCISC** register.

## Register 90: USB External Power Control Interrupt Mask (USBEPCIM), offset 0x408

**Host**

This 32-bit register specifies the interrupt mask of the two-pin external power interface.

**USB External Power Control Interrupt Mask (USBEPCIM)**
**Device**

Base 0x4005.0000

Offset 0x408

Type R/W, reset 0x0000.0000

**Bit/Field**      **Name**      **Type**      **Reset**      **Description**

31:1      reserved      RO      0x0000.000      Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0      PF      R/W      0      USB Power Fault Interrupt Mask

**Value**    **Description**

- 1      The raw interrupt signal from a detected power fault is sent to the interrupt controller.
- 0      A detected power fault does not affect the interrupt status.

## Register 91: USB External Power Control Interrupt Status and Clear (USBEPCISC), offset 0x40C

**Host**

This 32-bit register specifies the masked interrupt status of the two-pin external power interface. It also provides a method to clear the interrupt state.

**Device**

USB External Power Control Interrupt Status and Clear (USBEPCISC)

Base 0x4005.0000

Offset 0x40C

Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	PF	R/W1C	0	USB Power Fault Interrupt Status and Clear
Value	Description			
1	The <b>PF</b> bits in the <b>USBEPCRIS</b> and <b>USBEPCIM</b> registers are set, providing an interrupt to the interrupt controller.			
0	No interrupt has occurred or the interrupt is masked.			

This bit is cleared by writing a 1. Clearing this bit also clears the **PF** bit in the **USBEPCRIS** register.

## Register 92: USB Device RESUME Raw Interrupt Status (USBDRRIS), offset 0x410

### Host

The **USBDRRIS** 32-bit register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

### Device

USB Device RESUME Raw Interrupt Status (USBDRRIS)

Base 0x4005.0000

Offset 0x410

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	RESUME	RO	0	RESUME Interrupt Status

Value Description

- 1 A RESUME status has been detected.
- 0 An interrupt has not occurred.

This bit is cleared by writing a 1 to the RESUME bit in the **USBDRISC** register.

## Register 93: USB Device RESUME Interrupt Mask (USBDRIM), offset 0x414

**Host**

The **USBDRIM** 32-bit register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

**Device**

### USB Device RESUME Interrupt Mask (USBDRIM)

Base 0x4005.0000

Offset 0x414

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
------	----------	----	------	---

0	RESUME	R/W	0	RESUME Interrupt Mask
---	--------	-----	---	-----------------------

Value	Description
-------	-------------

1	The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the <b>USBIS</b> register is set).
0	A detected RESUME does not affect the interrupt status.

## Register 94: USB Device RESUME Interrupt Status and Clear (USBDRISC), offset 0x418

### Host

The **USBDRISC** 32-bit register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

### Device

USB Device RESUME Interrupt Status and Clear (USBDRISC)

Base 0x4005.0000

Offset 0x418

Type R/W1C, reset 0x0000.0000

Bit/Field      Name      Type      Reset      Description

31:1      reserved      RO      0x0000.0000      Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0      RESUME      R/W1C      0      RESUME Interrupt Status and Clear

Value      Description

- |   |   |
|---|---|
| 1 | The RESUME bits in the <b>USBDRRIS</b> and <b>USBDRCIM</b> registers are set, providing an interrupt to the interrupt controller. |
| 0 | No interrupt has occurred or the interrupt is masked.   |

This bit is cleared by writing a 1. Clearing this bit also clears the RESUME bit in the **USBDRCRIS** register.

## Register 95: USB General-Purpose Control and Status (USBGPCS), offset 0x41C

**Host**

**USBGPCS** provides the state of the internal ID signal.

USB General-Purpose Control and Status (USBGPCS)

**Device**

Base 0x4005.0000

Offset 0x41C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	DEVMOD	R/W	0	<b>Device Mode</b> This bit is used to control the state of the internal ID signal. In Device mode this bit is ignored (assumed set).

Value	Description
0	Host mode
1	Device mode

## 17 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See the Comparator Operating Mode tables in “Functional Description” on page 714 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The Stellaris® Analog Comparators module has the following features:

- Two independent integrated analog comparators
- Configurable for output to drive an output pin, generate an interrupt, or initiate an ADC sample sequence
- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of these voltages
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

## 17.1 Block Diagram

Figure 17-1. Analog Comparator Module Block Diagram

## 17.2 Functional Description

**Important:** It is recommended that the Digital-Input enable (the GPIODEN bit in the GPIO module) for the analog input pin be disabled to prevent excessive current draw from the I/O pads.

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$VIN_- < VIN_+$ ,  $VOUT = 1$   
 $VIN_- > VIN_+$ ,  $VOUT = 0$

As shown in Figure 17-2 on page 715, the input source for VIN- is an external input. In addition to an external input, input sources for VIN+ can be the +ve input of comparator 0 or an internal reference.

**Figure 17-2. Structure of Comparator Unit**

A comparator is configured through two status/control registers (**ACCTL** and **ACSTAT**). The internal reference is configured through one control register (**ACREFCTL**). Interrupt status and control is configured through three registers (**ACMIS**, **ACRIS**, and **ACINTEN**). The operating modes of the comparators are shown in the Comparator Operating Mode tables.

Typically, the comparator output is used internally to generate controller interrupts. It may also be used to drive an external pin or generate an analog-to-digital converter (ADC) trigger.

**Important:** The ASRCP bits in the **ACCTLn** register must be set before using the analog comparators. The proper pad configuration for the comparator input and output pins are described in the Comparator Operating Mode tables.

**Table 17-1. Comparator 0 Operating Modes**

ACCTL0	Comparator 0					
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger	
00	C0-	C0+	n/a	yes	yes	
01	C0-	C0+	n/a	yes	yes	
10	C0-	Vref	n/a	yes	yes	
11	C0-	reserved	n/a	yes	yes	

**Table 17-2. Comparator 1 Operating Modes**

ACCTL1	Comparator 1					
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger	
00	C1-	C1+	n/a	yes	yes	
01	C1-	C0+	n/a	yes	yes	
10	C1-	Vref	n/a	yes	yes	
11	C1-	reserved	n/a	yes	yes	

### 17.2.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 17-3 on page 716. This is controlled by a single configuration register (**ACREFCTL**). Table 17-3 on page 716 shows the programming options to develop specific internal reference values, to compare an external voltage against a particular voltage generated internally.

Figure 17-3. Comparator Internal Reference Structure

Table 17-3. Internal Reference Voltage and ACREFCTL Field Values

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=0	RNG=X	0 V (GND) for any value of VREF; however, it is recommended that RNG=1 and VREF=0 for the least noisy ground reference.
	RNG=0	<p>Total resistance in ladder is 31 R.</p> $V_{REF} = AV_{DD} \times \frac{R_{VREF}}{R_t}$ $V_{REF} = AV_{DD} \times \frac{(VREF + 8)}{31}$ $V_{REF} = 0.85 + 0.106 \times VREF$ <p>The range of internal reference in this mode is 0.85-2.448 V.</p>
EN=1	RNG=1	<p>Total resistance in ladder is 23 R.</p> $V_{REF} = AV_{DD} \times \frac{R_{VREF}}{R_t}$ $V_{REF} = AV_{DD} \times \frac{VREF}{23}$ $V_{REF} = 0.143 \times VREF$ <p>The range of internal reference for this mode is 0-2.152 V.</p>

## 17.3 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator 0 clock by writing a value of 0x0010.0000 to the **RCGC1** register in the System Control module.
2. In the GPIO module, enable the GPIO port/pin associated with C0– as a GPIO input.
3. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.

4. Configure comparator 0 to use the internal voltage reference and to *not* invert the output by writing the **ACCTL0** register with the value of 0x0000.040C.
5. Delay for some time.
6. Read the comparator output value by reading the **ACSTAT0** register's OVAL value.

Change the level of the signal input on C0– to see the OVAL value change.

## 17.4 Register Map

Table 17-4 on page 717 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000.

Note that the analog comparator module clock must be enabled before the registers can be programmed (see page 228). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 17-4. Analog Comparators Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	ACMIS	R/W1C	0x0000.0000	Analog Comparator Masked Interrupt Status	718
0x004	ACRIS	RO	0x0000.0000	Analog Comparator Raw Interrupt Status	719
0x008	ACINTEN	R/W	0x0000.0000	Analog Comparator Interrupt Enable	720
0x010	ACREFCTL	R/W	0x0000.0000	Analog Comparator Reference Voltage Control	721
0x020	ACSTAT0	RO	0x0000.0000	Analog Comparator Status 0	722
0x024	ACCTL0	R/W	0x0000.0000	Analog Comparator Control 0	723
0x040	ACSTAT1	RO	0x0000.0000	Analog Comparator Status 1	722
0x044	ACCTL1	R/W	0x0000.0000	Analog Comparator Control 1	723

## 17.5 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

## Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

## Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x000

Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	R/W1C	0	Comparator 1 Masked Interrupt Status Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.
0	IN0	R/W1C	0	Comparator 0 Masked Interrupt Status Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.

## Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparators.

### Analog Comparator Raw Interrupt Status (ACRIS)

Base 0x4003.C000  
Offset 0x004  
Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## 18 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The Stellaris® PWM module consists of four PWM generator blocks and a control block. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that can either be independent signals (other than being based on the same timer and therefore having the same frequency) or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins.

The Stellaris PWM module provides a great deal of flexibility. It can generate simple PWM signals, such as those required by a simple charge pump. It can also generate paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each Stellaris PWM module has the following features:

- Four PWM generator blocks, each with one 16-bit counter, two PWM comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector
- Four fault inputs in hardware to promote low-latency shutdown
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified

- Flexible output control block with PWM output enable of each PWM signal
  - PWM output enable of each PWM signal
  - Optional output inversion of each PWM signal (polarity control)
  - Optional fault handling for each PWM signal
  - Synchronization of timers in the PWM generator blocks
  - Synchronization of timer/comparator updates across the PWM generator blocks
  - Interrupt status summary of the PWM generator blocks
- Can initiate an ADC sample sequence

## 18.1 Block Diagram

Figure 18-1 on page 726 provides the Stellaris PWM module unit diagram and Figure 18-2 on page 727 provides a more detailed diagram of a Stellaris PWM generator. The LM3S3748 controller contains four generator blocks (PWM0, PWM1, PWM2, and PWM3) and generates eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

**Figure 18-1. PWM Unit Diagram**

**Figure 18-2. PWM Module Block Diagram**

## 18.2 Functional Description

### 18.2.1 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse.

### 18.2.2 PWM Comparators

There are two comparators in each PWM generator that monitor the value of the counter; when either match the counter, they output a single-clock-cycle-width High pulse. When in Count-Up/Down mode, these comparators match both when counting up and when counting down; they are therefore qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 18-3 on page 728 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 18-4 on page 728 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode.

**Figure 18-3. PWM Count-Down Mode****Figure 18-4. PWM Count-Up/Down Mode**

### 18.2.3 PWM Signal Generator

The PWM generator takes these pulses (qualified by the direction signal), and generates two PWM signals. In Count-Down mode, there are four events that can affect the PWM signal: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect the PWM signal: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, PWMA, is generated based only on the match A event, and the second signal, PWMB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 18-5 on page 729 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles.

**Figure 18-5. PWM Generation Example In Count-Up/Down Mode**

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the `PWMA` signal, and changing the value of comparator B changes the duty cycle of the `PWMB` signal.

#### 18.2.4 Dead-Band Generator

The two PWM signals produced by the PWM generator are passed to the dead-band generator. If disabled, the PWM signals simply pass through unmodified. If enabled, the second PWM signal is lost and two PWM signals are generated based on the first PWM signal. The first output PWM signal is the input signal with the rising edge delayed by a programmable amount. The second output PWM signal is the inversion of the input signal with a programmable delay added between the falling edge of the input signal and the rising edge of this new signal.

This is therefore a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 18-6 on page 729 shows the effect of the dead-band generator on an input PWM signal.

**Figure 18-6. PWM Dead-Band Generator**

#### 18.2.5 Interrupt/ADC-Trigger Selector

The PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position within the PWM signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

### 18.2.6 Synchronization Methods

The PWM unit provides four PWM generators providing eight PWM outputs that may be used in a wide variety of applications. Generally speaking, this falls into combinations of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used by itself, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base.

If multiple PWM generators are configured with the same counter load value, this can be used to guarantee that they also have the same count value (this does imply that the PWM generators must be configured before they are synchronized). With this, more than two PWM signals can be produced with a known relationship between the edges of those signals since the counters always have the same values. Other states in the unit provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM unit generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the `Sync` bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary `Sync` bits in one access. For example, setting the `Sync0` and `Sync1` bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additionally, the state of a PWM unit is affected by writing to the registers of the PWM unit and the PWM units' generators, which has an effect on the synchronization between multiple PWM generators. Depending on the register accessed, the register state is updated in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero. In this case, the effect of the write is deferred until the end of the PWM cycle (when the counter reaches zero). By waiting for the counter to reach zero, a guaranteed behavior is defined, and overly short or overly long output PWM pulses are prevented.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the global synchronization bit applicable to the generator is set, and (2) the counter reaches zero. In this case, the effect of the write is deferred until the end of the PWM cycle (when the counter reaches zero) following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of the **PWMnCTL** register `Update` bit value:

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect. The default update mode is immediate.

- Module-Level Register: **PWMENABLE**
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL**.

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization, and therefore, do not need synchronous update functionality.

### 18.2.7 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then sets the outputs to a safe state. There are two basic situations where this becomes necessary:

- The controller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected, such as an error

The PWM unit can use the following inputs to generate a fault condition, including:

- FAULTn pin assertion
- A stall of the controller generated by the debugger

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Each PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether a single FAULT0 input is used (as previous Stellaris products support) or whether all FAULTn input signals may be used to generate a fault condition. This register allows the fault condition duration to last as long as the external condition lasts, or it may specify that the external condition be latched and the fault condition (and its effects) last until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

These PWM generator registers provide status, control, and configure the fault condition in each PWM generator: **PWMnFLTSRC0**, **PWMnFLTSTAT0**, and **PWMnFLTSEN**.

There are up to four FAULT input pins (FAULT0-FAULT3). These pins may be used with circuits that generate an active High or active Low signal to indicate an error condition. Each of the FAULTn pins may be individually programmed for this logic sense using the **PWMnFLTSEN** register.

The **PWMnFLTSRC0** register define the contribution of the external fault sources. Using these registers, individual or groups of FAULTn signals are ORed together to specify the external fault generating conditions.

Status regarding the specific fault cause is provided in **PWMnFLTSTAT0**.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

During fault conditions, the PWM output signals usually require being driven to safe values so that external equipment may be safely controlled. To facilitate this, the **PWMFAULT** register is used to determine if the generated signal continues to be passed driven, or a specific fault condition encoding is driven on the PWM output, as specified in the **PWMFAULTVAL** register.

### 18.2.8 Output Control Block

With each PWM generator block producing two raw PWM signals, the output control block takes care of the final conditioning of the PWM signals before they go to the pins. Via a single register, the set of PWM signals that are actually enabled to the pins can be modified; this can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). Similarly, fault control can disable any of the PWM signals as well. A final inversion can be applied to any of the PWM signals, making them active Low instead of the default active High.

## 18.3 Initialization and Configuration

The following example shows how to initialize the PWM Generator 0 with a 25-KHz frequency, and with a 25% duty cycle on the `PWM0` pin and a 75% duty cycle on the `PWM1` pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by writing a value of 0x0010.0000 to the **RCGC0** register in the System Control module.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register.
4. Configure the **Run-Mode Clock Configuration (RCC)** register in the System Control module to use the PWM divide (`USEPWMDIV`) and set the divider (`PWMDIV`) to divide by 2 (000).
5. Configure the PWM generator for countdown mode with immediate updates to the parameters.
  - Write the **PWM0CTL** register with a value of 0x0000.0000.
  - Write the **PWM0GENA** register with a value of 0x0000.008C.
  - Write the **PWM0GENB** register with a value of 0x0000.080C.
6. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. This translates to 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the `Load` field in the **PWM0LOAD** register to the requested period minus one.
  - Write the **PWM0LOAD** register with a value of 0x0000.018F.
7. Set the pulse width of the `PWM0` pin for a 25% duty cycle.
  - Write the **PWM0CMPA** register with a value of 0x0000.012B.
8. Set the pulse width of the `PWM1` pin for a 75% duty cycle.
  - Write the **PWM0CMPB** register with a value of 0x0000.0063.
9. Start the timers in PWM generator 0.
  - Write the **PWM0CTL** register with a value of 0x0000.0001.
10. Enable PWM outputs.

- Write the **PWMENABLE** register with a value of 0x0000.0003.

## 18.4 Register Map

Table 18-1 on page 733 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM base address of 0x4002.8000. Note that the PWM module clock must be enabled before the registers can be programmed (see page 222). There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

**Table 18-1. PWM Register Map**

## 18.5 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

## Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation blocks.

### PWM Master Control (PWMCTL)

Base 0x4002.8000  
Offset 0x000  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	GlobalSync3	R/W	0	Update PWM Generator 3 Same as GlobalSync0 but for PWM generator 3.
2	GlobalSync2	R/W	0	Update PWM Generator 2 Same as GlobalSync0 but for PWM generator 2.
1	GlobalSync1	R/W	0	Update PWM Generator 1 Same as GlobalSync0 but for PWM generator 1.
0	GlobalSync0	R/W	0	Update PWM Generator 0 Setting this bit causes any queued update to a load or comparator register in PWM generator 0 to be applied the next time the corresponding counter becomes zero. This bit automatically clears when the updates have completed; it cannot be cleared by software.

## Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Writing a bit in this register to 1 causes the specified counter to reset back to 0; writing multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

### PWM Time Base Sync (PWMSYNC)

Base 0x4002.8000  
Offset 0x004  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	Sync3	R/W	0	Reset Generator 3 Counter Performs a reset of the PWM generator 3 counter.
2	Sync2	R/W	0	Reset Generator 2 Counter Performs a reset of the PWM generator 2 counter.
1	Sync1	R/W	0	Reset Generator 1 Counter Performs a reset of the PWM generator 1 counter.
0	Sync0	R/W	0	Reset Generator 0 Counter Performs a reset of the PWM generator 0 counter.

### Register 3: PWM Output Enable (PWMDENABLE), offset 0x008

This register provides a master control of which generated PWM signals are output to device pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding PWM signal is passed through to the output stage, which is controlled by the **PWMINVERT** register. When bits are not set, the PWM signal is replaced by a zero value which is also passed to the output stage.

#### PWM Output Enable (PWMDENABLE)

Base 0x4002.8000  
Offset 0x008  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RO	R/W														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	PWM7En	R/W	0	PWM7 Output Enable When set, allows the generated <code>PWM7</code> signal to be passed to the device pin.
6	PWM6En	R/W	0	PWM6 Output Enable When set, allows the generated <code>PWM6</code> signal to be passed to the device pin.
5	PWM5En	R/W	0	PWM5 Output Enable When set, allows the generated <code>PWM5</code> signal to be passed to the device pin.
4	PWM4En	R/W	0	PWM4 Output Enable When set, allows the generated <code>PWM4</code> signal to be passed to the device pin.
3	PWM3En	R/W	0	PWM3 Output Enable When set, allows the generated <code>PWM3</code> signal to be passed to the device pin.
2	PWM2En	R/W	0	PWM2 Output Enable When set, allows the generated <code>PWM2</code> signal to be passed to the device pin.
1	PWM1En	R/W	0	PWM1 Output Enable When set, allows the generated <code>PWM1</code> signal to be passed to the device pin.

Bit/Field	Name	Type	Reset	Description
0	PWM0En	R/W	0	PWM0 Output Enable When set, allows the generated PWM0 signal to be passed to the device pin.

## Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the PWM signals on the device pins. The PWM signals generated by the PWM generator are active High; they can optionally be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive channels maintain the correct polarity.

### PWM Output Inversion (PWMINVERT)

Base 0x4002.8000  
Offset 0x00C  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	R/W								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	PWM7Inv	R/W	0	Invert PWM7 Signal When set, the generated PWM7 signal is inverted.
6	PWM6Inv	R/W	0	Invert PWM6 Signal When set, the generated PWM6 signal is inverted.
5	PWM5Inv	R/W	0	Invert PWM5 Signal When set, the generated PWM5 signal is inverted.
4	PWM4Inv	R/W	0	Invert PWM4 Signal When set, the generated PWM4 signal is inverted.
3	PWM3Inv	R/W	0	Invert PWM3 Signal When set, the generated PWM3 signal is inverted.
2	PWM2Inv	R/W	0	Invert PWM2 Signal When set, the generated PWM2 signal is inverted.
1	PWM1Inv	R/W	0	Invert PWM1 Signal When set, the generated PWM1 signal is inverted.
0	PWM0Inv	R/W	0	Invert PWM0 Signal When set, the generated PWM0 signal is inverted.

## Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the PWM outputs in the presence of fault conditions. Both the fault inputs and debug events are considered fault conditions. On a fault condition, each PWM signal can be passed through unmodified or driven to a specified value. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the PWM signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

### PWM Output Fault (PWMFAULT)

Base 0x4002.8000  
Offset 0x010  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	reserved								Fault7	Fault6	Fault5	Fault4	Fault3	Fault2	Fault1	Fault0
Type	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	Fault7	R/W	0	PWM7 Fault When set, the PWM7 output signal is driven to a specified value on a fault condition.
6	Fault6	R/W	0	PWM6 Fault When set, the PWM6 output signal is driven to a specified value on a fault condition.
5	Fault5	R/W	0	PWM5 Fault When set, the PWM5 output signal is driven to a specified value on a fault condition.
4	Fault4	R/W	0	PWM4 Fault When set, the PWM4 output signal is driven to a specified value on a fault condition.
3	Fault3	R/W	0	PWM3 Fault When set, the PWM3 output signal is driven to a specified value on a fault condition.
2	Fault2	R/W	0	PWM2 Fault When set, the PWM2 output signal is driven to a specified value on a fault condition.
1	Fault1	R/W	0	PWM1 Fault When set, the PWM1 output signal is driven to a specified value on a fault condition.

Bit/Field	Name	Type	Reset	Description
0	Fault0	R/W	0	PWM0 Fault When set, the PWM0 output signal is driven to a specified value on a fault condition.

## Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

### PWM Interrupt Enable (PWMINTEN)

Base 0x4002.8000  
Offset 0x014  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RO	R/W	R/W	R/W	R/W											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RO	R/W	R/W	R/W	R/W											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:20	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	IntFault3	R/W	0	Interrupt Fault 3 When set, an interrupt occurs when the fault condition for PWM generator 3 is asserted.
18	IntFault2	R/W	0	Interrupt Fault 2 When set, an interrupt occurs when the fault condition for PWM generator 2 is asserted.
17	IntFault1	R/W	0	Interrupt Fault 1 When set, an interrupt occurs when the fault condition for PWM generator 1 is asserted.
16	IntFault0	R/W	0	Interrupt Fault 0 When set, an interrupt occurs when the FAULT0 input is asserted or the fault condition for PWM generator 0 is asserted.
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntPWM3	R/W	0	PWM3 Interrupt Enable When set, an interrupt occurs when the PWM generator 3 block asserts an interrupt.
2	IntPWM2	R/W	0	PWM2 Interrupt Enable When set, an interrupt occurs when the PWM generator 2 block asserts an interrupt.
1	IntPWM1	R/W	0	PWM1 Interrupt Enable When set, an interrupt occurs when the PWM generator 1 block asserts an interrupt.
0	IntPWM0	R/W	0	PWM0 Interrupt Enable When set, an interrupt occurs when the PWM generator 0 block asserts an interrupt.

## Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller. The fault interrupt is latched on detection; it must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register (see page 745). The PWM generator interrupts simply reflect the status of the PWM generators; they are cleared via the interrupt status register in the PWM generator blocks. Bits set to 1 indicate the events that are active; zero bits indicate that the event in question is not active.

### PWM Raw Interrupt Status (PWMRIS)

Base 0x4002.8000  
Offset 0x018  
Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RO	IntFault3	IntFault2	IntFault1	IntFault0											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RO	IntPWM3	IntPWM2	IntPWM1	IntPWM0											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:20	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	IntFault3	RO	0	Interrupt Fault PWM 3 Indicates that the fault condition for PWM generator 3 is asserting.
18	IntFault2	RO	0	Interrupt Fault PWM 2 Indicates that the fault condition for PWM generator 2 is asserting.
17	IntFault1	RO	0	Interrupt Fault PWM 1 Indicates that the fault condition for PWM generator 1 is asserting.
16	IntFault0	RO	0	Interrupt Fault PWM 0 Indicates that the FAULT0 input is asserting or the fault condition for PWM generator 0 is asserting.
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntPWM3	RO	0	PWM3 Interrupt Asserted Indicates that the PWM generator 3 block is asserting its interrupt.
2	IntPWM2	RO	0	PWM2 Interrupt Asserted Indicates that the PWM generator 2 block is asserting its interrupt.
1	IntPWM1	RO	0	PWM1 Interrupt Asserted Indicates that the PWM generator 1 block is asserting its interrupt.
0	IntPWM0	RO	0	PWM0 Interrupt Asserted Indicates that the PWM generator 0 block is asserting its interrupt.

## Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. A bit set to 1 indicates that the corresponding generator block is asserting an interrupt. The individual interrupt status registers in each block must be consulted to determine the reason for the interrupt, and used to clear the interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status.

### PWM Interrupt Status and Clear (PWMISC)

Base 0x4002.8000  
Offset 0x01C  
Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved												IntFault3	IntFault2	IntFault1	IntFault0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved												IntPWM3	IntPWM2	IntPWM1	IntPWM0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:20	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	IntFault3	R/W1C	0	FAULT3 Interrupt Asserted Indicates that the FAULT3 input is asserting or the FAULT3 latch has captured an assertion.
18	IntFault2	R/W1C	0	FAULT2 Interrupt Asserted Indicates that the FAULT2 input is asserting or the FAULT2 latch has captured an assertion.
17	IntFault1	R/W1C	0	FAULT1 Interrupt Asserted Indicates that the FAULT1 input is asserting or the FAULT1 latch has captured an assertion.
16	IntFault0	R/W1C	0	FAULT0 Interrupt Asserted Indicates that the FAULT0 input is asserting or the fault condition for generator 0 is asserting a fault.
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntPWM3	RO	0	PWM3 Interrupt Status Indicates if the PWM generator 3 block is asserting an interrupt.
2	IntPWM2	RO	0	PWM2 Interrupt Status Indicates if the PWM generator 2 block is asserting an interrupt.
1	IntPWM1	RO	0	PWM1 Interrupt Status Indicates if the PWM generator 1 block is asserting an interrupt.
0	IntPWM0	RO	0	PWM0 Interrupt Status Indicates if the PWM generator 0 block is asserting an interrupt.

**Register 9: PWM Status (PWMSTATUS), offset 0x020**

This register provides the status of the FAULT input signals.

**PWM Status (PWMSTATUS)**

Base 0x4002.8000  
Offset 0x020  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	Fault3	RO	0	Fault3 Interrupt Status When set, indicates the fault condition for PWM generator 3 is asserted.
2	Fault2	RO	0	Fault2 Interrupt Status When set, indicates the fault condition for PWM generator 2 is asserted.
1	Fault1	RO	0	Fault1 Interrupt Status When set, indicates the fault condition for PWM generator 1 is asserted.
0	Fault0	RO	0	Fault0 Interrupt Status When set, indicates the FAULT0 input is asserted, or that the fault condition for PWM generator 0 is asserted.

## Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024

This register specifies the output value driven on the PWM signals during a fault condition if the corresponding bit in the **PWMFAULT** register is indicating that the PWM signal drives a value.

### PWM Fault Condition Value (PWMFAULTVAL)

Base 0x4002.8000

7	PWM7	R/W	0	PWM7 Fault Value The PWM7 output signal is driven to the value specified in this bit during fault conditions if the Fault7 bit in the <b>PWMFAULT</b> register is set.
6	PWM6	R/W	0	PWM6 Fault Value The PWM6 output signal is driven to the value specified in this bit during fault conditions if the Fault6 bit in the <b>PWMFAULT</b> register is set.
5	PWM5	R/W	0	PWM5 Fault Value The PWM5 output signal is driven to the value specified in this bit during fault conditions if the Fault5 bit in the <b>PWMFAULT</b> register is set.
4	PWM4	R/W	0	PWM4 Fault Value The PWM4 output signal is driven to the value specified in this bit during fault conditions if the Fault4 bit in the <b>PWMFAULT</b> register is set.
3	PWM3	R/W	0	PWM3 Fault Value The PWM3 output signal is driven to the value specified in this bit during fault conditions if the Fault3 bit in the <b>PWMFAULT</b> register is set.
2	PWM2	R/W	0	PWM2 Fault Value The PWM2 output signal is driven to the value specified in this bit during fault conditions if the Fault2 bit in the <b>PWMFAULT</b> register is set.
1	PWM1	R/W	0	PWM1 Fault Value The PWM1 output signal is driven to the value specified in this bit during fault conditions if the Fault1 bit in the <b>PWMFAULT</b> register is set.
0	PWM0	R/W	0	PWM0 Fault Value The PWM0 output signal is driven to the value specified in this bit during fault conditions if the Fault0 bit in the <b>PWMFAULT</b> register is set.

**Register 11: PWM0 Control (PWM0CTL), offset 0x040****Register 12: PWM1 Control (PWM1CTL), offset 0x080****Register 13: PWM2 Control (PWM2CTL), offset 0x0C0****Register 14: PWM3 Control (PWM3CTL), offset 0x100**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the `PWM0` and `PWM1` outputs, the PWM1 block produces the `PWM2` and `PWM3` outputs, the PWM2 block produces the `PWM4` and `PWM5` outputs, and the PWM3 block produces the `PWM6` and `PWM7` outputs.

Bit/Field	Name	Type	Reset	Description
31:19	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
18	LATCH	R/W	0	<p>Latch Fault Input</p> <p>This bit controls the behavior of the fault condition in a PWM generator. The fault condition may be latched and internally asserted because the fault condition logic includes the generator's <code>IntFaultn</code> bit (of the <b>PWMISC</b> register) enabled by the <code>LATCH</code> bit.</p> <p>Therefore, if the <b>PWMINTEN</b> <code>IntFaultn</code> bit is set, a fault condition sets the <b>PWMISC</b> <code>IntFaultn</code> bit (generating an interrupt) and the fault condition is extended in the generator logic until software clears the <b>PWMISC</b> <code>IntFaultn</code> bit.</p>

Value	Description
0	Fault Condition Not Latched A fault condition is in effect for as long as the generating source is asserting.
1	Fault Condition Latched A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the <b>PWMISC</b> <code>IntFaultn</code> bit is set. Clearing the <code>IntFaultn</code> bit clears the fault condition.

Bit/Field	Name	Type	Reset	Description										
17	MINFLTPER	R/W	0	<p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the <b>PWMnMINFLTPER</b> register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is PWMClock * (MFP value + 1) or PWMClock * (MFP value + 2).</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Fault Condition Period Not Extended The FAULT input deassertion is unaffected.</td></tr> <tr> <td>1</td><td>Fault Condition Period Extended The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.</td></tr> </tbody> </table>	Value	Description	0	Fault Condition Period Not Extended The FAULT input deassertion is unaffected.	1	Fault Condition Period Extended The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.

7:6	GenAUpd	R/W	0	<b>PWMnGENA</b> Update Mode Specifies the update mode for the <b>PWMnGENA</b> register. <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Immediate The <b>PWMnGENA</b> register value is immediately updated on a write.</td></tr> <tr> <td>1</td><td>Reserved</td></tr> <tr> <td>2</td><td>Locally Synchronized Updates to the register are reflected to the generator the next time the counter is 0.</td></tr> <tr> <td>3</td><td>Globally Synchronized Updates to the register are delayed until the next time the counter is 0 after a synchronous update has been requested through the PWM Master Control (<b>PWMCTL</b>) register.</td></tr> </tbody> </table>	Value	Description	0	Immediate The <b>PWMnGENA</b> register value is immediately updated on a write.	1	Reserved	2	Locally Synchronized Updates to the register are reflected to the generator the next time the counter is 0.	3	Globally Synchronized Updates to the register are delayed until the next time the counter is 0 after a synchronous update has been requested through the PWM Master Control ( <b>PWMCTL</b> ) register.
Value	Description													
0	Immediate The <b>PWMnGENA</b> register value is immediately updated on a write.													
1	Reserved													
2	Locally Synchronized Updates to the register are reflected to the generator the next time the counter is 0.													
3	Globally Synchronized Updates to the register are delayed until the next time the counter is 0 after a synchronous update has been requested through the PWM Master Control ( <b>PWMCTL</b> ) register.													
5	CmpBUpd	R/W	0	Comparator B Update Mode Same as <b>CmpAUpd</b> but for the comparator B register.										
4	CmpAUpd	R/W	0	Comparator A Update Mode The Update mode for the comparator A register. When not set, updates to the register are reflected to the comparator the next time the counter is 0. When set, updates to the register are delayed until the next time the counter is 0 after a synchronous update has been requested through the <b>PWM Master Control (PWMCTL)</b> register (see page 736).										
3	LoadUpd	R/W	0	Load Register Update Mode The Update mode for the load register. When not set, updates to the register are reflected to the counter the next time the counter is 0. When set, updates to the register are delayed until the next time the counter is 0 after a synchronous update has been requested through the <b>PWM Master Control (PWMCTL)</b> register.										
2	Debug	R/W	0	Debug Mode The behavior of the counter in Debug mode. When not set, the counter stops running when it next reaches 0, and continues running again when no longer in Debug mode. When set, the counter always runs.										
1	Mode	R/W	0	Counter Mode The mode for the counter. When not set, the counter counts down from the load value to 0 and then wraps back to the load value (Count-Down mode). When set, the counter counts up from 0 to the load value, back down to 0, and then repeats (Count-Up/Down mode).										
0	Enable	R/W	0	PWM Block Enable Master enable for the PWM generation block. When not set, the entire block is disabled and not clocked. When set, the block is enabled and produces PWM signals.										

**Register 15: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044****Register 16: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084****Register 17: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4****Register 18: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104**

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the comparator A register while counting up
- The counter being equal to the comparator A register while counting down
- The counter being equal to the comparator B register while counting up
- The counter being equal to the comparator B register while counting down

Any combination of these events can generate either an interrupt, or an ADC trigger; though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified.

**PWM0 Interrupt and Trigger Enable (PWM0INTEN)**

5	IntCmpBD	R/W1C	0	Comparator B Down Interrupt Indicates that the counter has matched the comparator B value while counting down.
4	IntCmpBU	R/W1C	0	Comparator B Up Interrupt Indicates that the counter has matched the comparator B value while counting up.
3	IntCmpAD	R/W1C	0	Comparator A Down Interrupt Indicates that the counter has matched the comparator A value while counting down.
2	IntCmpAU	R/W1C	0	Comparator A Up Interrupt Indicates that the counter has matched the comparator A value while counting up.
1	IntCntLoad	R/W1C	0	Counter=Load Interrupt Indicates that the counter has matched the <b>PWMnLOAD</b> register.
0	IntCntZero	R/W1C	0	Counter=0 Interrupt Indicates that the counter has matched 0.

**Register 27: PWM0 Load (PWM0LOAD), offset 0x050****Register 28: PWM1 Load (PWM1LOAD), offset 0x090****Register 29: PWM2 Load (PWM2LOAD), offset 0x0D0****Register 30: PWM3 Load (PWM3LOAD), offset 0x110**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode, either this value is loaded into the counter after it reaches zero, or it is the limit of up-counting after which the counter decrements back to zero.

If the Load Value Update mode is immediate, this value is used the next time the counter reaches zero; if the mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 736). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Load	R/W	0	Counter Load Value The counter load value.

**Register 31: PWM0 Counter (PWM0COUNT), offset 0x054****Register 32: PWM1 Counter (PWM1COUNT), offset 0x094****Register 33: PWM2 Counter (PWM2COUNT), offset 0x0D4****Register 34: PWM3 Counter (PWM3COUNT), offset 0x114**

These registers contain the current value of the PWM counter. When this value matches the load register, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers, see page 761 and page 764) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register, see page 752). A pulse with the same capabilities is generated when this value is zero.

## PWM0 Counter (PWM0COUNT)

Base 0x4002.8000  
Offset 0x054  
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Count	RO	0x00	Counter Value The current value of the counter.

**Register 35: PWM0 Compare A (PWM0CMPA), offset 0x058****Register 36: PWM1 Compare A (PWM1CMPA), offset 0x098****Register 37: PWM2 Compare A (PWM2CMPA), offset 0x0D8****Register 38: PWM3 Compare A (PWM3CMPA), offset 0x118**

These registers contain a value to be compared against the counter (PWM0CMPA controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 757), then no pulse is ever output.

If the comparator A update mode is immediate (based on the CmpAUUpd bit in the **PWMnCTL** register), this 16-bit CompA value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMMCTL)** register (see page 736). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompB	R/W	0x00	Comparator B Value The value to be compared against the counter.

**Register 43: PWM0 Generator A Control (PWM0GENA), offset 0x060****Register 44: PWM1 Generator A Control (PWM1GENA), offset 0x0A0****Register 45: PWM2 Generator A Control (PWM2GENA), offset 0x0E0****Register 46: PWM3 Generator A Control (PWM3GENA), offset 0x120**

These registers control the generation of the  $\text{PWM}_{nA}$  signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENA** register controls generation of the **PWM0A** signal; **PWM1GENA**, the **PWM1A** signal; **PWM2GENA**, the **PWM2A** signal; and **PWM3GENA**, the **PWM3A** signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the **GenAUpd** field encoding in the **PWMnCTL** register), this 16-bit **GenAUpd** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCCTL)** register (see page 736). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 47: PWM0 Generator B Control (PWM0GENB), offset 0x064****Register 48: PWM1 Generator B Control (PWM1GENB), offset 0x0A4****Register 49: PWM2 Generator B Control (PWM2GENB), offset 0x0E4****Register 50: PWM3 Generator B Control (PWM3GENB), offset 0x124**

These registers control the generation of the `PWMnB` signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Down mode, only four of these events occur; when running in Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENB** register controls generation of the `PWM0B` signal; **PWM1GENB**, the `PWM1B` signal; **PWM2GENB**, the `PWM2B` signal; and **PWM3GENB**, the `PWM3B` signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the `GenBUpd` field encoding in the **PWMnCTL** register), this 16-bit `GenBUpd` value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 736). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 51: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068****Register 52: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8****Register 53: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8****Register 54: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128**

The **PWM0DBCTL** register controls the dead-band generator, which produces the PWM0 and PWM1 signals based on the PWM0A and PWM0B signals. When disabled, the PWM0A signal passes through to the PWM0 signal and the PWM0B signal passes through to the PWM1 signal. When enabled and inverting the resulting waveform, the PWM0B signal is ignored; the PWM0 signal is generated by delaying the rising edge(s) of the PWM0A signal by the value in the **PWM0DBRISE** register (see page 768), and the PWM1 signal is generated by delaying the falling edge(s) of the PWM0A signal by the value in the **PWM0DBFALL** register (see page 769). In a similar manner, PWM2 and PWM3 are produced from the PWM1A and PWM1B signals, PWM4 and PWM5 are produced from the PWM2A and PWM2B signals, and PWM6 and PWM7 are produced from the PWM3A and PWM3B signals.

If the Dead-Band Control mode is immediate (based on the DBCtl1Upd field encoding in the **PWMnCTL** register), this 16-bit DBCtl1Upd value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 736). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Dead-Band Control (PWM0DBCTL)**

Base 0x4002.8000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Enable	R/W	0	Dead-Band Generator Enable When set, the dead-band generator inserts dead bands into the output signals; when clear, it simply passes the PWM signals through.

**Register 55: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C**

**Register 56: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC**

**Register 57: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC**

**Register 58: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C**

The **PWM0DBRISE** register contains the number of clock ticks to delay the rising edge of the **PWM0A** signal when generating the **PWM0** signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, the **PWM0DBRISE** register is ignored. If the value of this register is larger than the width of a High pulse on the input PWM signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the input High time always exceeds the rising-edge delay. In a similar manner, **PWM2** is generated from **PWM1A** with its rising edge delayed; **PWM4** is produced from **PWM2A** with its rising edge delayed; and **PWM6** is produced from **PWM3A** with its rising edge delayed.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the **DBRiseUpd** field encoding in the **PWMnCTL** register), this 16-bit **DBRiseUpd** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 736). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	RiseDelay	R/W	0	Dead-Band Rise Delay The number of clock ticks to delay the rising edge.

**Register 59: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070**

**Register 60: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0**

**Register 61: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0**

**Register 62: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130**

The **PWM0DBFALL** register contains the number of clock ticks to delay the falling edge of the **PWM0A** signal when generating the **PWM1** signal. If the dead-band generator is disabled, this register is ignored. If the value of this register is larger than the width of a Low pulse on the input PWM signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the input Low time always exceeds the falling-edge delay. In a similar manner, **PWM3** is generated from **PWM1A** with its falling edge delayed, **PWM5** is produced from **PWM2A** with its falling edge delayed, and **PWM7** is produced from **PWM3A** with its falling edge delayed.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the **DBFallUp** field encoding in the **PWMnCTL** register), this 16-bit **DBFallUp** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 736). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

#### PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL)

Base 0x4002.8000

**Register 63: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074****Register 64: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4****Register 65: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4****Register 66: PWM3 Fault Source 0 (PWM3FLTSRC0), offset 0x134**

This register specifies which fault pin inputs are used to indicate a fault condition. Each bit in the following register indicates whether the corresponding fault pin is included in the fault condition. All enabled fault pins are ORed together to form the **PWM<sub>n</sub>FLTSRC0** portion of the fault condition. The **PWM<sub>n</sub>FLTSRC0** fault condition is then ORed with the **PWM<sub>n</sub>FLTSRC1** fault condition to generate the final fault condition for the PWM generator.

If the **FLTSRC** bit in the **PWM<sub>n</sub>CTL** register (see page 748) is clear, only the **PWM Fault0** pin affects the fault condition generated. Otherwise, sources defined in **PWM<sub>n</sub>FLTSRC0** and **PWM<sub>n</sub>FLTSRC1** affect the fault condition generated.

## PWM0 Fault Source 0 (PWM0FLTSRC0)

Base 0x4002.8000  
Offset 0x074  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

3	FAULT3	R/W	0	Fault3 The same function as Fault0, except applied for the FAULT3 input.  <b>Note:</b> The FLTSRC bit in the <b>PWM<sub>n</sub>CTL</b> register must be set for this bit to affect fault condition generation.
2	FAULT2	R/W	0	Fault2 The same function as Fault0, except applied for the FAULT2 input.  <b>Note:</b> The FLTSRC bit in the <b>PWM<sub>n</sub>CTL</b> register must be set for this bit to affect fault condition generation.
1	FAULT1	R/W	0	Fault1 The same function as Fault0, except applied for the FAULT1 input.  <b>Note:</b> The FLTSRC bit in the <b>PWM<sub>n</sub>CTL</b> register must be set for this bit to affect fault condition generation.

Bit/Field	Name	Type	Reset	Description
0	FAULT0	R/W	0	Fault0 Specifies the contribution of the FAULT0 input to the generation of a fault condition.
Value Description				
0 Suppressed The FAULT0 signal is suppressed and cannot generate a fault condition.				
1 Generated The FAULT0 signal value is ORed with all other fault condition generation inputs (Fault signals).				

**Register 67: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C****Register 68: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC****Register 69: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC****Register 70: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C**

If the MINFLTPER bit in the **PWMnCTL** register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

0	FAULT0	R/W	0	Fault0 Sense This bit specifies the sense of the <code>FAULT0</code> input pin, and it determines what sense is considered asserted, that is, the sense of the input (High or Low) that indicates error.

Value	Description
0	High
1	Low The fault sense is used to translate the incoming <code>FAULT0</code> pin signal sense to an internal positive signal.

**Register 75: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804****Register 76: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884****Register 77: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904****Register 78: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the **FAULTn** inputs.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (R/W1C) and provide a latched version of the **FAULTn** inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The **FAULTn** inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

# 19 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The Stellaris® quadrature encoder interface (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The Stellaris quadrature encoder has the following features:

- Position integrator that tracks the encoder position
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

## 19.1 Block Diagram

Figure 19-1 on page 777 provides a block diagram of a Stellaris QEI module.

**Figure 19-1. QEI Block Diagram**

## 19.2 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals, PhA and PhB, can be swapped before being interpreted by the QEI module to change the meaning of forward and backward, and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the **SigMode** bit of the **QEI Control (QEICTL)** register (see page 781).

When the QEI module is set to use the quadrature phase mode (**SigMode** bit equals zero), the capture mode for the position integrator can be set to update the position counter on every edge of the PhA signal or to update on every edge of both PhA and PhB. Updating the position counter on every PhA and PhB provides more positional resolution at the cost of less range in the positional counter.

When edges on PhA lead edges on PhB, the position counter is incremented. When edges on PhB lead edges on PhA, the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. Which mode is determined by the **ResMode** bit of the **QEI Control (QEICTL)** register.

When **ResMode** is 1, the positional counter is reset when the index pulse is sensed. This limits the positional counter to the values [0:N-1], where N is the number of phase edges in a full revolution of the encoder wheel. The **QEIMAXPOS** register must be programmed with N-1 so that the reverse direction from position 0 can move the position counter to N-1. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When **ResMode** is 0, the positional counter is constrained to the range [0:M], where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

The velocity capture has a configurable timer and a count register. It counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QEISPEED** register, while the edge count for the current time period is being accumulated in the **QEICOUNT** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (losing the previous value), the **QEICOUNT** is reset to 0, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 19-2 on page 778 shows how the Stellaris quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

**Figure 19-2. Quadrature Encoder and Velocity Predivider Operation**

The period of the timer is configurable by specifying the load value for the timer in the **QEILoad** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILoad** value and continues to count down. At lower encoder speeds, a longer timer period is needed to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

$$\text{rpm} = (\text{clock} * (2 ^ \text{VelDiv}) * \text{Speed} * 60) / (\text{Load} * \text{ppr} * \text{edges})$$

where:

**clock** is the controller clock rate

**ppr** is the number of pulses per revolution of the physical encoder

**edges** is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for **CapMode** set to 0 and 4 for **CapMode** set to 1)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of

$\div 1$  (VelDiv set to 0) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 ( $\frac{1}{4}$  of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every  $\frac{1}{4}$  of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation since intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the  $\div 4$  for the edge-count factor.

**Important:** Reducing constant factors at compile time is the best way to control the intermediate values of this equation, as well as reducing the processing requirement of computing this equation.

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, this is a simple matter of selecting a power of 2 load value. For other encoders, a load value must be selected such that the product is very close to a power of two. For example, a 100 pulse per revolution encoder could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above  $2^{14}$ ; in this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the controller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

## 19.3 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock by writing a value of 0x0000.0100 to the **RCGC1** register in the System Control module.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register.
4. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. Using a 1000-line encoder at four edges per line, there are 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) since the count is zero-based.
  - Write the **QEICTL** register with the value of 0x0000.0018.

- Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
- 5. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
- 6. Delay for some time.
- 7. Read the encoder position by reading the **QEIPOS** register value.

## 19.4 Register Map

Table 19-1 on page 780 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEI0: 0x4002.C000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 228). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

## 19.5 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

## Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
1	Direction	RO	0	<p>Direction of Rotation Indicates the direction the encoder is rotating. The <b>Direction</b> values are defined as follows:</p> <table border="0"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Forward rotation</td> </tr> <tr> <td>1</td> <td>Reverse rotation</td> </tr> </tbody> </table>	Value	Description	0	Forward rotation	1	Reverse rotation
Value	Description									
0	Forward rotation									
1	Reverse rotation									
0	Error	RO	0	<p>Error Detected Indicates that an error was detected in the gray code sequence (that is, both signals changing at the same time).</p>						

### Register 3: QEI Position (QEIPOS), offset 0x008

This register contains the current value of the position integrator. Its value is updated by inputs on the QEI phase inputs, and can be set to a specific value by writing to it.

#### QEI Position (QEIPOS)

QEI0 base: 0x4002.C000

Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	Position	R/W	0x00	Current Position Integrator Value The current value of the position integrator.
------	----------	-----	------	--

## Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving backward, the position register resets to this value when it decrements from zero.

### QEI Maximum Position (QEIMAXPOS)

QEIO base: 0x4002.C000

Offset 0x00C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	MaxPos	R/W	0x00	Maximum Position Integrator Value The maximum value of the position integrator.

## Register 5: QEI Timer Load (QEILOAD), offset 0x010

This register contains the load value for the velocity timer. Since this value is loaded into the timer the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 clocks per timer period, this register should contain 1999.

### QEI Timer Load (QEILOAD)

QEI0 base: 0x4002.C000

Offset 0x010

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Load	R/W	0x00	Velocity Timer Load Value The load value for the velocity timer.

## Register 6: QEI Timer (QEITIME), offset 0x014

This register contains the current value of the velocity timer. This counter does not increment when **VelEn** in **QEICTL** is 0.

### QEI Timer (QEITIME)

QEI0 base: 0x4002.C000

Offset 0x014

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	Time	RO	0x00	Velocity Timer Current Value The current value of the velocity timer.
------	------	----	------	--

## Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018

This register contains the running count of velocity pulses for the current time period. Since this is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register since there is a small window of time between the two reads, during which time either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when **VelEn** in **QEICTL** is 0.

### QEI Velocity Counter (QEICOUNT)

QEI0 base: 0x4002.C000

Offset 0x018

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Count	RO	0x00	Velocity Pulse Count The running total of encoder pulses during this velocity timer period.

## Register 8: QEI Velocity (QEISPEED), offset 0x01C

This register contains the most recently measured velocity of the quadrature encoder. This corresponds to the number of velocity pulses counted in the previous velocity timer period. This register does not update when **VelEn** in **QEICTL** is 0.

### QEI Velocity (QEISPEED)

QEIO base: 0x4002.C000

Offset 0x01C

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Speed	RO	0x00	Velocity The measured speed of the quadrature encoder in pulses per period.

## Register 9: QEI Interrupt Enable (QEINTEN), offset 0x020

This register contains enables for each of the QEI module's interrupts. An interrupt is asserted to the controller if its corresponding bit in this register is set to 1.

### QEI Interrupt Enable (QEINTEN)

QEI0 base: 0x4002.C000  
Offset 0x020  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntError	R/W	0	Phase Error Interrupt Enable When 1, an interrupt occurs when a phase error is detected.
2	IntDir	R/W	0	Direction Change Interrupt Enable When 1, an interrupt occurs when the direction changes.
1	IntTimer	R/W	0	Timer Expires Interrupt Enable When 1, an interrupt occurs when the velocity timer expires.
0	IntIndex	R/W	0	Index Pulse Detected Interrupt Enable When 1, an interrupt occurs when the index pulse is detected.

## Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (this is set through the **QEINTEN** register). Bits set to 1 indicate the latched events that have occurred; a zero bit indicates that the event in question has not occurred.

### QEI Raw Interrupt Status (QEIRIS)

QEI0 base: 0x4002.C000

Offset 0x024

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntError	RO	0	Phase Error Detected Indicates that a phase error was detected.
2	IntDir	RO	0	Direction Change Detected Indicates that the direction has changed.
1	IntTimer	RO	0	Velocity Timer Expired Indicates that the velocity timer has expired.
0	IntIndex	RO	0	Index Pulse Asserted Indicates that the index pulse has occurred.

## Register 11: QEI Interrupt Status and Clear (QEIIISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. Bits set to 1 indicate the latched events that have occurred; a zero bit indicates that the event in question has not occurred. This is a R/W1C register; writing a 1 to a bit position clears the corresponding interrupt reason.

### QEI Interrupt Status and Clear (QEIIISC)

QEI0 base: 0x4002.C000

Offset 0x028

Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntError	R/W1C	0	Phase Error Interrupt Indicates that a phase error was detected.
2	IntDir	R/W1C	0	Direction Change Interrupt Indicates that the direction has changed.
1	IntTimer	R/W1C	0	Velocity Timer Expired Interrupt Indicates that the velocity timer has expired.
0	IntIndex	R/W1C	0	Index Pulse Interrupt Indicates that the index pulse has occurred.

## 20 Pin Diagram

The LM3S3748 microcontroller pin diagram is shown below.

**Figure 20-1. 100-Pin LQFP Package Pin Diagram**

# 21 Signal Tables

The following tables list the signals available for each pin. Functionality is enabled by software with the **GPIOAFSEL** register.

**Important:** All multiplexed pins are GPIOs by default, with the exception of the four JTAG pins ( $\text{PC}[3:0]$ ) which default to the JTAG functionality.

Table 21-1 on page 794 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Table 21-2 on page 798 lists the signals in alphabetical order by signal name.

Table 21-3 on page 803 groups the signals by functionality, except for GPIOs. Table 21-4 on page 806 lists the GPIO pins and their alternate functionality.

**Note:** All digital inputs are Schmitt triggered.

**Table 21-1. Signals by Pin Number**

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
1	PE7	I/O	TTL	GPIO port E bit 7.
	ADC0	I	Analog	Analog-to-digital converter input 0.
2	PE6	I/O	TTL	GPIO port E bit 6.
	ADC1	I	Analog	Analog-to-digital converter input 1.
3	VDDA	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.
4	GND <sub>A</sub>	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
5	PE5	I/O	TTL	GPIO port E bit 5.
	ADC2	I	Analog	Analog-to-digital converter input 2.
6	PE4	I/O	TTL	GPIO port E bit 4.
	ADC3	I	Analog	Analog-to-digital converter input 3.
7	LDO	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu\text{F}$ or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
8	VDD	-	Power	Positive supply for I/O and some logic.
9	GND	-	Power	Ground reference for logic and I/O pins.
10	PD0	I/O	TTL	GPIO port D bit 0.
	IDX0	I	TTL	QEI module 0 index.
11	PD1	I/O	TTL	GPIO port D bit 1.
	PhA0	I	TTL	QEI module 0 phase A.
12	PD2	I/O	TTL	GPIO port D bit 2.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
13	PD3	I/O	TTL	GPIO port D bit 3.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.

**Table 21-1. Signals by Pin Number (continued)**

<b>Pin Number</b>	<b>Pin Name</b>	<b>Pin Type</b>	<b>Buffer Type<sup>a</sup></b>	<b>Description</b>
14	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
15	GND	-	Power	Ground reference for logic and I/O pins.
16	PG3	I/O	TTL	GPIO port G bit 3.
	Fault2	I	TTL	PWM Fault 2.
17	PG2	I/O	TTL	GPIO port G bit 2.
18	PG1	I/O	TTL	GPIO port G bit 1.
	PWM5	O	TTL	PWM 5. This signal is controlled by PWM Generator 2.
19	PG0	I/O	TTL	GPIO port G bit 0.
	PWM4	O	TTL	PWM 4. This signal is controlled by PWM Generator 2.
20	VDD	-	Power	Positive supply for I/O and some logic.
21	GND	-	Power	Ground reference for logic and I/O pins.
22	PC7	I/O	TTL	GPIO port C bit 7.
	U1Tx	O	TTL	UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.
23	PC6	I/O	TTL	GPIO port C bit 6.
	U1Rx	I	TTL	UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.
24	PC5	I/O	TTL	GPIO port C bit 5.
	C1+	I	Analog	Analog comparator 1 positive input.
25	PC4	I/O	TTL	GPIO port C bit 4.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
26	PA0	I/O	TTL	GPIO port A bit 0.
	U0Rx	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
27	PA1	I/O	TTL	GPIO port A bit 1.
	U0Tx	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
28	PA2	I/O	TTL	GPIO port A bit 2.
	SSI0Clk	I/O	TTL	SSI module 0 clock.
29	PA3	I/O	TTL	GPIO port A bit 3.
	SSI0FSS	I/O	TTL	SSI module 0 frame.
30	PA4	I/O	TTL	GPIO port A bit 4.
	SSI0Rx	I	TTL	SSI module 0 receive.
31	PA5	I/O	TTL	GPIO port A bit 5.
	SSI0Tx	O	TTL	SSI module 0 transmit.
32	VDD	-	Power	Positive supply for I/O and some logic.
33	GND	-	Power	Ground reference for logic and I/O pins.
34	PA6	I/O	TTL	GPIO port A bit 6.
	I2C1SCL	I/O	OD	I <sup>2</sup> C module 1 clock.
35	PA7	I/O	TTL	GPIO port A bit 7.
	I2C1SDA	I/O	OD	I <sup>2</sup> C module 1 data.

**Table 21-1. Signals by Pin Number (continued)**

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
36	PG7	I/O	TTL	GPIO port G bit 7.
	PWM7	O	TTL	PWM 7. This signal is controlled by PWM Generator 3.
37	PG6	I/O	TTL	GPIO port G bit 6.
	PWM6	O	TTL	PWM 6. This signal is controlled by PWM Generator 3.
38	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
39	GND	-	Power	Ground reference for logic and I/O pins.
40	PG5	I/O	TTL	GPIO port G bit 5.
	Fault1	I	TTL	PWM Fault 1.
41	PG4	I/O	TTL	GPIO port G bit 4.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
42	PF7	I/O	TTL	GPIO port F bit 7.
	PhB0	I	TTL	QEI module 0 phase B.
43	PF6	I/O	TTL	GPIO port F bit 6.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
44	VDD	-	Power	Positive supply for I/O and some logic.
45	GND	-	Power	Ground reference for logic and I/O pins.
46	PF5	I/O	TTL	GPIO port F bit 5.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
47	PF0	I/O	TTL	GPIO port F bit 0.
	PWM0	O	TTL	PWM 0. This signal is controlled by PWM Generator 0.
48	OSCO	I	Analog	Main oscillator crystal input or an external clock reference input.
49	OSC1	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
50	WAKE	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
51	HIB	O	OD	An open-drain output that indicates the processor is in Hibernate mode.
52	XOSCO	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
53	XOSC1	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.
54	GND	-	Power	Ground reference for logic and I/O pins.
55	VBAT	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
56	VDD	-	Power	Positive supply for I/O and some logic.
57	GND	-	Power	Ground reference for logic and I/O pins.
58	PF4	I/O	TTL	GPIO port F bit 4.
	Fault0	I	TTL	PWM Fault 0.
59	PF3	I/O	TTL	GPIO port F bit 3.
	PWM3	O	TTL	PWM 3. This signal is controlled by PWM Generator 1.

**Table 21-1. Signals by Pin Number (continued)**

<b>Pin Number</b>	<b>Pin Name</b>	<b>Pin Type</b>	<b>Buffer Type<sup>a</sup></b>	<b>Description</b>
60	PF2	I/O	TTL	GPIO port F bit 2.
	PWM2	O	TTL	PWM 2. This signal is controlled by PWM Generator 1.
61	PF1	I/O	TTL	GPIO port F bit 1.
	PWM1	O	TTL	PWM 1. This signal is controlled by PWM Generator 0.
62	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
63	GND	-	Power	Ground reference for logic and I/O pins.
64	RST	I	TTL	System reset input.
65	PB3	I/O	TTL	GPIO port B bit 3.
	I2C0SDA	I/O	OD	I <sup>2</sup> C module 0 data.
66	PB0	I/O	TTL	GPIO port B bit 0.
67	PB1	I/O	TTL	GPIO port B bit 1.
68	VDD	-	Power	Positive supply for I/O and some logic.
69	GND	-	Power	Ground reference for logic and I/O pins.
70	USB0DM	I/O	Analog	Bidirectional differential data pin (D- per USB specification).
71	USB0DP	I/O	Analog	Bidirectional differential data pin (D+ per USB specification).
72	PB2	I/O	TTL	GPIO port B bit 2.
	I2C0SCL	I/O	OD	I <sup>2</sup> C module 0 clock.
73	USB0RBIAS	O	Analog	9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.
74	PE0	I/O	TTL	GPIO port E bit 0.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
75	PE1	I/O	TTL	GPIO port E bit 1.
	SSI1FSS	I/O	TTL	SSI module 1 frame.
76	PH4	I/O	TTL	GPIO port H bit 4.
	USB0PFLT	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
77	PC3	I/O	TTL	GPIO port C bit 3.
	SWO	O	TTL	JTAG TDO and SWO.
	TDO	O	TTL	JTAG TDO and SWO.
78	PC2	I/O	TTL	GPIO port C bit 2.
	TDI	I	TTL	JTAG TDI.
79	PC1	I/O	TTL	GPIO port C bit 1.
	SWDIO	I/O	TTL	JTAG TMS and SWDIO.
	TMS	I/O	TTL	JTAG TMS and SWDIO.
80	PC0	I/O	TTL	GPIO port C bit 0.
	SWCLK	I	TTL	JTAG/SWD CLK.
	TCK	I	TTL	JTAG/SWD CLK.
81	VDD	-	Power	Positive supply for I/O and some logic.
82	GND	-	Power	Ground reference for logic and I/O pins.

**Table 21-1. Signals by Pin Number (continued)**

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
83	PH3	I/O	TTL	GPIO port H bit 3.
	USB0EOPEN	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
84	PH2	I/O	TTL	GPIO port H bit 2.
	Fault3	I	TTL	PWM Fault 3.
85	PH1	I/O	TTL	GPIO port H bit 1.
	CCP7	I/O	TTL	Capture/Compare/PWM 7.
86	PH0	I/O	TTL	GPIO port H bit 0.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
87	GND	-	Power	Ground reference for logic and I/O pins.
88	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
89	PB7	I/O	TTL	GPIO port B bit 7.
	NMI	I	TTL	Non-maskable interrupt.
90	PB6	I/O	TTL	GPIO port B bit 6.
	C0+	I	Analog	Analog comparator 0 positive input.
91	PB5	I/O	TTL	GPIO port B bit 5.
	C1-	I	Analog	Analog comparator 1 negative input.
92	PB4	I/O	TTL	GPIO port B bit 4.
	C0-	I	Analog	Analog comparator 0 negative input.
93	VDD	-	Power	Positive supply for I/O and some logic.
94	GND	-	Power	Ground reference for logic and I/O pins.
95	PE2	I/O	TTL	GPIO port E bit 2.
	SSI1Rx	I	TTL	SSI module 1 receive.
96	PE3	I/O	TTL	GPIO port E bit 3.
	SSI1Tx	O	TTL	SSI module 1 transmit.
97	PD4	I/O	TTL	GPIO port D bit 4.
	ADC7	I	Analog	Analog-to-digital converter input 7.
98	PD5	I/O	TTL	GPIO port D bit 5.
	ADC6	I	Analog	Analog-to-digital converter input 6.
99	PD6	I/O	TTL	GPIO port D bit 6.
	ADC5	I	Analog	Analog-to-digital converter input 5.
100	PD7	I/O	TTL	GPIO port D bit 7.
	ADC4	I	Analog	Analog-to-digital converter input 4.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

**Table 21-2. Signals by Signal Name**

Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
ADC0	1	I	Analog	Analog-to-digital converter input 0.
ADC1	2	I	Analog	Analog-to-digital converter input 1.
ADC2	5	I	Analog	Analog-to-digital converter input 2.
ADC3	6	I	Analog	Analog-to-digital converter input 3.

**Table 21-2. Signals by Signal Name (*continued*)**

Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
ADC4	100	I	Analog	Analog-to-digital converter input 4.
ADC5	99	I	Analog	Analog-to-digital converter input 5.
ADC6	98	I	Analog	Analog-to-digital converter input 6.
ADC7	97	I	Analog	Analog-to-digital converter input 7.
C0+	90	I	Analog	Analog comparator 0 positive input.
C0-	92	I	Analog	Analog comparator 0 negative input.
C1+	24	I	Analog	Analog comparator 1 positive input.
C1-	91	I	Analog	Analog comparator 1 negative input.
CCP0	13	I/O	TTL	Capture/Compare/PWM 0.
CCP1	43	I/O	TTL	Capture/Compare/PWM 1.
CCP2	46	I/O	TTL	Capture/Compare/PWM 2.

Fault1	40	I	TTL	PWM Fault 1.
Fault2	16	I	TTL	PWM Fault 2.
Fault3	84	I	TTL	PWM Fault 3.
GND	9 15 21 33 39 45 54 57 63 69 82 87 94	-	Power	Ground reference for logic and I/O pins.
GNDA	4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
HIB	51	O	OD	An open-drain output that indicates the processor is in Hibernate mode.
I2C0SCL	72	I/O	OD	I <sup>2</sup> C module 0 clock.
I2C0SDA	65	I/O	OD	I <sup>2</sup> C module 0 data.
I2C1SCL	34	I/O	OD	I <sup>2</sup> C module 1 clock.
I2C1SDA	35	I/O	OD	I <sup>2</sup> C module 1 data.
IDX0	10	I	TTL	QEI module 0 index.

**Table 21-2. Signals by Signal Name (*continued*)**

Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
NMI	89	I	TTL	Non-maskable interrupt.
OSC0	48	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	49	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
PA0	26	I/O	TTL	GPIO port A bit 0.
PA1	27	I/O	TTL	GPIO port A bit 1.
PA2	28	I/O	TTL	GPIO port A bit 2.
PA3	29	I/O	TTL	GPIO port A bit 3.
PA4	30	I/O	TTL	GPIO port A bit 4.
PA5	31	I/O	TTL	GPIO port A bit 5.
PA6	34	I/O	TTL	GPIO port A bit 6.
PA7	35	I/O	TTL	GPIO port A bit 7.
PB0	66	I/O	TTL	GPIO port B bit 0.
PB1	67	I/O	TTL	GPIO port B bit 1.
PB2	72	I/O	TTL	GPIO port B bit 2.

**Table 21-2. Signals by Signal Name (*continued*)**

<b>Pin Name</b>	<b>Pin Number</b>	<b>Pin Type</b>	<b>Buffer Type<sup>a</sup></b>	<b>Description</b>
SSI0FSS	29	I/O	TTL	SSI module 0 frame.
SSI0RX	30	I	TTL	SSI module 0 receive.
SSI0TX	31	O	TTL	SSI module 0 transmit.
SSI1Clk	74	I/O	TTL	SSI module 1 clock.
SSI1FSS	75	I/O	TTL	SSI module 1 frame.
SSI1RX	95	I	TTL	SSI module 1 receive.
SSI1TX	96	O	TTL	SSI module 1 transmit.
SWCLK	80	I	TTL	JTAG/SWD CLK.
SWDIO	79	I/O	TTL	JTAG TMS and SWDIO.
SWO	77	O	TTL	JTAG TDO and SWO.
TCK	80	I	TTL	JTAG/SWD CLK.
TDI	78	I	TTL	JTAG TDI.
TDO	77	O	TTL	JTAG TDO and SWO.
TMS	79	I/O	TTL	JTAG TMS and SWDIO.
U0Rx	26	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
U0Tx	27	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
U1Rx	23	I	TTL	UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.
U1Tx	22	O	TTL	UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.
USB0DM	70	I/O	Analog	Bidirectional differential data pin (D- per USB specification).
USB0DP	71	I/O	Analog	Bidirectional differential data pin (D+ per USB specification).
USBOEPEN	83	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
USB0PFLT	76	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
USB0RBIAS	73	O	Analog	9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.
VBAT	55	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
VDD	8 20 32 44 56 68 81 93	-	Power	Positive supply for I/O and some logic.
VDD25	14 38 62 88	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.

**Table 21-2. Signals by Signal Name (*continued*)**

Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
VDDA	3	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.
WAKE	50	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
XOSC0	52	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
XOSC1	53	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

**Table 21-3. Signals by Function, Except for GPIO**

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
ADC	ADC0	1	I	Analog	Analog-to-digital converter input 0.
	ADC1	2	I	Analog	Analog-to-digital converter input 1.
	ADC2	5	I	Analog	Analog-to-digital converter input 2.
	ADC3	6	I	Analog	Analog-to-digital converter input 3.
	ADC4	100	I	Analog	Analog-to-digital converter input 4.
	ADC5	99	I	Analog	Analog-to-digital converter input 5.
	ADC6	98	I	Analog	Analog-to-digital converter input 6.
	ADC7	97	I	Analog	Analog-to-digital converter input 7.
Analog Comparators	C0+	90	I	Analog	Analog comparator 0 positive input.
	C0-	92	I	Analog	Analog comparator 0 negative input.
	C1+	24	I	Analog	Analog comparator 1 positive input.
	C1-	91	I	Analog	Analog comparator 1 negative input.
General-Purpose Timers	CCP0	13	I/O	TTL	Capture/Compare/PWM 0.
	CCP1	43	I/O	TTL	Capture/Compare/PWM 1.
	CCP2	46	I/O	TTL	Capture/Compare/PWM 2.
	CCP3	41	I/O	TTL	Capture/Compare/PWM 3.
	CCP4	25	I/O	TTL	Capture/Compare/PWM 4.
	CCP5	12	I/O	TTL	Capture/Compare/PWM 5.
	CCP6	86	I/O	TTL	Capture/Compare/PWM 6.
	CCP7	85	I/O	TTL	Capture/Compare/PWM 7.

**Table 21-3. Signals by Function, Except for GPIO (continued)**

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
Hibernate	HIB	51	O	OD	An open-drain output that indicates the processor is in Hibernate mode.
	VBAT	55	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
	WAKE	50	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
	XOSC0	52	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
	XOSC1	53	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

	Fault1	40	I	TTL	PWM Fault 1.
	Fault2	16	I	TTL	PWM Fault 2.
	Fault3	84	I	TTL	PWM Fault 3.
	PWM0	47	O	TTL	PWM 0. This signal is controlled by PWM Generator 0.
	PWM1	61	O	TTL	PWM 1. This signal is controlled by PWM Generator 0.
	PWM2	60	O	TTL	PWM 2. This signal is controlled by PWM Generator 1.
	PWM3	59	O	TTL	PWM 3. This signal is controlled by PWM Generator 1.
	PWM4	19	O	TTL	PWM 4. This signal is controlled by PWM Generator 2.
	PWM5	18	O	TTL	PWM 5. This signal is controlled by PWM Generator 2.
	PWM6	37	O	TTL	PWM 6. This signal is controlled by PWM Generator 3.
	PWM7	36	O	TTL	PWM 7. This signal is controlled by PWM Generator 3.

**Table 21-3. Signals by Function, Except for GPIO (continued)**

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
Power	GND	9 15 21 33 39 45 54 57 63 69 82 87 94	-	Power	Ground reference for logic and I/O pins.
	GNDA	4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
	VDD	8 20 32 44 56 68 81 93	-	Power	Positive supply for I/O and some logic.
	VDD25	14 38 62 88	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
	VDDA	3	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.
QEI	IDX0	10	I	TTL	QEI module 0 index.
	PhA0	11	I	TTL	QEI module 0 phase A.
	PhB0	42	I	TTL	QEI module 0 phase B.
SSI	SSI0Clk	28	I/O	TTL	SSI module 0 clock.
	SSI0Fss	29	I/O	TTL	SSI module 0 frame.
	SSI0Rx	30	I	TTL	SSI module 0 receive.
	SSI0Tx	31	O	TTL	SSI module 0 transmit.
	SSI1Clk	74	I/O	TTL	SSI module 1 clock.
	SSI1Fss	75	I/O	TTL	SSI module 1 frame.
	SSI1Rx	95	I	TTL	SSI module 1 receive.
	SSI1Tx	96	O	TTL	SSI module 1 transmit.

**Table 21-3. Signals by Function, Except for GPIO (continued)**

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
System Control & Clocks	NMI	89	I	TTL	Non-maskable interrupt.
	OSC0	48	I	Analog	Main oscillator crystal input or an external clock reference input.
	OSC1	49	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
	RST	64	I	TTL	System reset input.
UART	U0Rx	26	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
	U0Tx	27	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
	U1Rx	23	I	TTL	UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.
	U1Tx	22	O	TTL	UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.
USB	USB0DM	70	I/O	Analog	Bidirectional differential data pin (D- per USB specification).
	USB0DP	71	I/O	Analog	Bidirectional differential data pin (D+ per USB specification).
	USB0EPEN	83	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
	USB0PFLT	76	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
	USB0RBIAS	73	O	Analog	9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 21.1 Connections for Unused Signals

Table 21-5 on page 808 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 100-pin LQFP package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

**Table 21-5. Connections for Unused Signals (100-pin LQFP)**

Function	Signal Name	Pin Number	Acceptable Practice	Preferred Practice
GPIO	All unused GPIOs	-	NC	GND
Hibernate	HIB	51	NC	NC
	VBAT	55	NC	GND
	WAKE	50	NC	GND
	XOSC0	52	NC	GND
	XOSC1	53	NC	NC
No Connects	NC	-	NC	NC
System Control	OSC0	48	NC	GND
	OSC1	49	NC	NC
	RST	48	Pull up as shown in Figure 5-1 on page 175	Connect through a capacitor to GND as close to pin as possible
USB	USB0RBIAS	73	Connect to GND through 10-kΩ resistor.	Connect to GND through 10-kΩ resistor.
	USB0DM	70	NC	GND
	USB0DP	71	NC	GND

## 22 Operating Characteristics

**Table 22-1. Temperature Characteristics**

Characteristic	Symbol	Value	Unit
Industrial operating temperature range	T <sub>A</sub>	-40 to +85	°C
Unpowered storage temperature range	T <sub>S</sub>	-65 to +150	°C

**Table 22-2. Thermal Characteristics**

Characteristic	Symbol	Value	Unit
Thermal resistance (junction to ambient) <sup>a</sup>	θ <sub>JA</sub>	32	°C/W
Junction temperature <sup>b</sup>	T <sub>J</sub>	T <sub>A</sub> + (P • θ <sub>JA</sub> )	°C

a. Junction to ambient thermal resistance θ<sub>JA</sub> numbers are determined by a package simulator.

b. Power dissipation is a function of temperature.

**Table 22-3. ESD Absolute Maximum Ratings<sup>a</sup>**

Parameter Name	Min	Nom	Max	Unit
V <sub>ESDHBM</sub>	-	-	2.0	kV
V <sub>ESDCDM</sub>	-	-	1.0	kV
V <sub>ESDMM</sub>	-	-	100	V

a. All Stellaris parts are ESD tested following the JEDEC standard.

# 23 Electrical Characteristics

## 23.1 DC Characteristics

### 23.1.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 23-1. Maximum Ratings**

Characteristic <sup>a</sup>	Symbol	Value		Unit
		Min	Max	
I/O supply voltage ( $V_{DD}$ )	$V_{DD}$	0	4	V
Core supply voltage ( $V_{DD25}$ )	$V_{DD25}$	0	3	V
Analog supply voltage ( $V_{DDA}$ )	$V_{DDA}$	0	4	V
Battery supply voltage ( $V_{BAT}$ )	$V_{BAT}$	0	4	V
Input voltage	$V_{IN}$	-0.3	5.5	V
Input voltage for a GPIO configured as an analog input		-0.3	$V_{DD} + 0.3$	V
Maximum current per output pins	I	-	25	mA
Maximum input voltage on a non-power pin when the microcontroller is unpowered	$V_{NON}$	-	300	mV

a. Voltages are measured with respect to GND.

**Important:** This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either GND or  $V_{DD}$ ).

### 23.1.2 Recommended DC Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the  $V_{OL}$  value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

**Table 23-2. Recommended DC Operating Conditions**

Parameter	Parameter Name	Min	Nom	Max	Unit
$V_{DD}$	I/O supply voltage	3.0	3.3	3.6	V
$V_{DD25}$	Core supply voltage	2.25	2.5	2.75	V
$V_{DDA}$	Analog supply voltage	3.0	3.3	3.6	V
$V_{BAT}$	Battery supply voltage	2.3	3.0	3.6	V
$V_{IH}$	High-level input voltage	2.0	-	5.0	V
$V_{IL}$	Low-level input voltage	-0.3	-	1.3	V

**Table 23-2. Recommended DC Operating Conditions (continued)**

Parameter	Parameter Name	Min	Nom	Max	Unit
$V_{OH}^a$	High-level output voltage	2.4	-	-	V
$V_{OL}^a$	Low-level output voltage	-	-	0.4	V
$I_{OH}$	High-level source current, $V_{OH}=2.4$ V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
$I_{OL}$	Low-level sink current, $V_{OL}=0.4$ V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA

a.  $V_{OL}$  and  $V_{OH}$  shift to 1.2 V when using high-current GPIOs.

### 23.1.3 On-Chip Low Drop-Out (LDO) Regulator Characteristics

**Table 23-3. LDO Regulator Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
$V_{LDOOUT}$	Programmable internal (logic) power supply output value	2.25	2.5	2.75	V
	Output voltage accuracy	-	2%	-	%
$t_{PON}$	Power-on time	-	-	100	$\mu$ s
$t_{ON}$	Time on	-	-	200	$\mu$ s
$t_{OFF}$	Time off	-	-	100	$\mu$ s
$V_{STEP}$	Step programming incremental voltage	-	50	-	mV
$C_{LDO}$	External filter capacitor size for internal power supply	1.0	-	3.0	$\mu$ F

### 23.1.4 GPIO Module Characteristics

**Table 23-4. GPIO Module DC Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
$R_{GPIOPU}$	GPIO internal pull-up resistor	50	-	110	k $\Omega$
$R_{GPIOPD}$	GPIO internal pull-down resistor	55	-	180	k $\Omega$
$I_{LKG}$	GPIO input leakage current <sup>a</sup>	-	-	2	$\mu$ A

a. The leakage current is measured with GND or  $V_{DD}$  applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pullup/pulldown resistor is disabled.

### 23.1.5 Power Specifications

The power measurements specified in the tables that follow are run on the core processor using SRAM with the following specifications (except as noted):

- $V_{DD} = 3.3$  V
- $V_{DD25} = 2.50$  V

- $V_{BAT} = 3.0 \text{ V}$
- $V_{DDA} = 3.3 \text{ V}$
- Temperature =  $25^\circ\text{C}$
- Clock Source (MOSC) = 3.579545 MHz Crystal Oscillator
- Main oscillator (MOSC) = enabled
- Internal oscillator (IOSC) = disabled

**Table 23-5. Detailed Power Specifications**

Parameter	Parameter Name	Conditions	3.3 V $V_{DD}, V_{DDA}$		2.5 V $V_{DD25}$		3.0 V $V_{BAT}$		Unit
			Nom	Max	Nom	Max	Nom	Max	
$I_{DD\_RUN}$	Run mode 1 (Flash loop)	$V_{DD25} = 2.50 \text{ V}$ Code= while(1){} executed in Flash Peripherals = All ON System Clock = 50 MHz (with PLL)	9.5	pending <sup>a</sup>	108	pending <sup>a</sup>	0	pending <sup>a</sup>	mA

a. Pending characterization completion.

### 23.1.6 Flash Memory Characteristics

**Table 23-6. Flash Memory Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
$PE_{CYC}$	Number of guaranteed program/erase cycles before failure <sup>a</sup>	10,000	100,000	-	cycles
$T_{RET}$	Data retention at average operating temperature of 85°C	10	-	-	years
$T_{PROG}$	Word program time	20	-	-	μs
$T_{ERASE}$	Page erase time	20	-	-	ms
$T_{ME}$	Mass erase time	-	-	250	ms

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

### 23.1.7 Hibernation

**Table 23-7. Hibernation Module DC Characteristics**

Parameter	Parameter Name	Value	Unit
$V_{LOWBAT}$	Low battery detect voltage	2.35	V
$R_{WAKEPU}$	$\overline{WAKE}$ internal pull-up resistor	200	kΩ

### 23.1.8 USB

The Stellaris® USB controller DC electrical specifications are compliant with the “Universal Serial Bus Specification Rev. 2.0” (full-speed and low-speed support). Some components of the USB system are integrated within the LM3S3748 microcontroller and specific to the Stellaris microcontroller design. These components are specified in Table 23-8 on page 813.

**Table 23-8. USB Controller DC Characteristics**

Parameter	Parameter Name	Value	Unit
$R_{BIAS}$	Value of the pull-down resistor on the $USB0RBIAS$ pin	$9.1K \pm 1\%$	Ω

## 23.2 AC Characteristics

### 23.2.1 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements. Timing measurements are for 4-mA drive strength.

**Figure 23-1. Load Conditions**

### 23.2.2 Clocks

**Table 23-9. Phase Locked Loop (PLL) Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
$f_{ref\_crystal}$	Crystal reference <sup>a</sup>	3.579545	-	16.384	MHz
$f_{ref\_ext}$	External clock reference <sup>a</sup>	3.579545	-	16.384	MHz
$f_{pll}$	PLL frequency <sup>b</sup>	-	400	-	MHz
$T_{READY}$	PLL lock time	-	-	0.5	ms

a. The exact value is determined by the crystal value programmed into the XTAL field of the **Run-Mode Clock Configuration (RCC)** register.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

Table 23-10 on page 814 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

**Table 23-10. Actual PLL Frequency**

XTAL	Crystal Frequency (MHz)	PLL Frequency (MHz)	Error
0x04	3.5795	400.904	0.0023%
0x05	3.6864	398.1312	0.0047%
0x06	4.0	400	-
0x07	4.096	401.408	0.0035%
0x08	4.9152	398.1312	0.0047%
0x09	5.0	400	-
0x0A	5.12	399.36	0.0016%
0x0B	6.0	400	-
0x0C	6.144	399.36	0.0016%
0x0D	7.3728	398.1312	0.0047%
0x0E	8.0	400	0.0047%
0x0F	8.192	398.6773333	0.0033%
0x10	10.0	400	-
0x11	12.0	400	-
0x12	12.288	401.408	0.0035%
0x13	13.56	397.76	0.0056%
0x14	14.318	400.90904	0.0023%
0x15	16.0	400	-
0x16	16.384	404.1386667	0.010%

**Table 23-11. Clock Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
$f_{iosc}$	Internal 12 MHz oscillator frequency	8.4	12	15.6	MHz
$f_{iosc30KHZ}$	Internal 30 KHz oscillator frequency	15	30	45	KHz
$f_{xosc}$	Hibernation module oscillator frequency	-	4.194304	-	MHz
$f_{xosc_xtal}$	Crystal reference for hibernation oscillator	-	4.194304	-	MHz
$f_{xosc_ext}$	External clock reference for hibernation module	-	32.768	-	KHz

**Table 23-11. Clock Characteristics (continued)**

Parameter	Parameter Name	Min	Nom	Max	Unit
$f_{MOSC}$	Main oscillator frequency	1	-	16.384	MHz
$t_{MOSC\_per}$	Main oscillator period	61	-	1000	ns
$f_{ref\_crystal\_bypass}$	Crystal reference using the main oscillator (PLL in BYPASS mode) <sup>a</sup>	1	-	16.384	MHz
$f_{ref\_ext\_bypass}$	External clock reference (PLL in BYPASS mode) <sup>a</sup>	0	-	50	MHz
$f_{system\_clock}$	System clock	0	-	50	MHz

a. The ADC must be clocked from the PLL or directly from a 16-MHz clock source to operate properly.

**Table 23-12. Crystal Characteristics**

Parameter Name	Value						Units
Frequency	16	12	8	6	4	3.5	MHz
Frequency tolerance	$\pm 50$	ppm					
Aging	$\pm 5$	ppm/yr					
Oscillation mode	Parallel	Parallel	Parallel	Parallel	Parallel	Parallel	-
Temperature stability (-40°C to 85°C)	$\pm 25$	ppm					
Motional capacitance (typ)	13.9	18.5	27.8	37.0	55.6	63.5	pF
Motional inductance (typ)	7.15	9.5	14.3	19.1	28.6	32.7	mH
Equivalent series resistance (max)	80	100	120	160	200	220	$\Omega$
Shunt capacitance (max)	10	10	10	10	10	10	pF
Load capacitance (typ)	16	16	16	16	16	16	pF
Drive level (typ)	100	100	100	100	100	100	$\mu W$

### 23.2.2.1 System Clock Specifications with ADC Operation

**Table 23-13. System Clock Characteristics with ADC Operation**

Parameter	Parameter Name	Min	Nom	Max	Unit
$f_{sysadc}$	System clock frequency when the ADC module is operating (when PLL is bypassed)	16	-	-	MHz

### 23.2.3 JTAG and Boundary Scan

**Table 23-14. JTAG Characteristics**

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
J1	$f_{TCK}$	TCK operational clock frequency	0	-	10	MHz
J2	$t_{TCK}$	TCK operational clock period	100	-	-	ns
J3	$t_{TCK\_LOW}$	TCK clock Low time	-	$t_{TCK}$	-	ns
J4	$t_{TCK\_HIGH}$	TCK clock High time	-	$t_{TCK}$	-	ns
J5	$t_{TCK\_R}$	TCK rise time	0	-	10	ns
J6	$t_{TCK\_F}$	TCK fall time	0	-	10	ns
J7	$t_{TMS\_SU}$	TMS setup time to TCK rise	20	-	-	ns

**Table 23-14. JTAG Characteristics (continued)**

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
J8	$t_{TMS\_HLD}$	TMS hold time from TCK rise	20	-	-	ns
J9	$t_{TDI\_SU}$	TDI setup time to TCK rise	25	-	-	ns
J10	$t_{TDI\_HLD}$	TDI hold time from TCK rise	25	-	-	ns
J11 $t_{TDO\_ZDV}$	TCK fall to Data Valid from High-Z	2-mA drive	-	23	35	ns
		4-mA drive		15	26	ns
		8-mA drive		14	25	ns
		8-mA drive with slew rate control		18	29	ns
J12 $t_{TDO\_DV}$	TCK fall to Data Valid from Data Valid	2-mA drive	-	21	35	ns
		4-mA drive		14	25	ns
		8-mA drive		13	24	ns
		8-mA drive with slew rate control		18	28	ns
J13 $t_{TDO\_DVZ}$	TCK fall to High-Z from Data Valid	2-mA drive	-	9	11	ns
		4-mA drive		7	9	ns
		8-mA drive		6	8	ns
		8-mA drive with slew rate control		7	9	ns

**Figure 23-2. JTAG Test Clock Input Timing****Figure 23-3. JTAG Test Access Port (TAP) Timing**

### 23.2.4 Reset

**Table 23-15. Reset Characteristics**

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
R1	$V_{TH}$	Reset threshold	-	2.0	-	V
R2	$V_{BTH}$	Brown-Out threshold	2.85	2.9	2.95	V
R3	$T_{POR}$	Power-On Reset timeout	-	10	-	ms
R4	$T_{BOR}$	Brown-Out timeout	-	500	-	$\mu$ s
R5	$T_{IRPOR}$	Internal reset timeout after POR	6	-	11	ms
R6	$T_{IRBOR}$	Internal reset timeout after BOR <sup>a</sup>	0	-	1	$\mu$ s
R7	$T_{IRHWR}$	Internal reset timeout after hardware reset ( $\overline{RST}$ pin)	0	-	1	ms
R8	$T_{IRSWR}$	Internal reset timeout after software-initiated system reset <sup>a</sup>	2.5	-	20	$\mu$ s
R9	$T_{IRWDR}$	Internal reset timeout after watchdog reset <sup>a</sup>	2.5	-	20	$\mu$ s
R10	$T_{VDDRISE}$	Supply voltage ( $V_{DD}$ ) rise time (0V-3.3V), power on reset	-	-	100	ms
		Supply voltage ( $V_{DD}$ ) rise time (0V-3.3V), waking from hibernation	-	-	250	$\mu$ s
R11	$T_{MIN}$	Minimum $\overline{RST}$ pulse width	2	-	-	$\mu$ s

a.  $20 * t_{MOSC\_per}$

**Figure 23-4. External Reset Timing ( $\overline{RST}$ )**

**Figure 23-5. Power-On Reset Timing**

**Figure 23-6. Brown-Out Reset Timing****Figure 23-7. Software Reset Timing****Figure 23-8. Watchdog Reset Timing**

### 23.2.5 Sleep Modes

**Table 23-16. Sleep Modes AC Characteristics<sup>a</sup>**

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
D1	$t_{WAKE\_S}$	Time to wake from interrupt in sleep or deep-sleep mode, not using the PLL	-	-	7	system clocks
D2	$t_{WAKE\_PLL\_S}$	Time to wake from interrupt in sleep or deep-sleep mode when using the PLL	-	-	TREADY	ms

a. Values in this table assume the IOSC is the clock source during sleep or deep-sleep mode.

### 23.2.6 Hibernation Module

The Hibernation Module requires special system implementation considerations since it is intended to power-down all other sections of its host device. The system power-supply distribution and interfaces to the device must be driven to 0 V<sub>DC</sub> or powered down with the same external voltage regulator controlled by  $\overline{HIB}$ .

The external voltage regulators controlled by  $\overline{HIB}$  must have a settling time of 250  $\mu$ s or less.

**Table 23-17. Hibernation Module AC Characteristics**

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
H1	$t_{HIB\_LOW}$	Internal 32.768 KHz clock reference rising edge to /HIB asserted	-	200	-	$\mu s$
H2	$t_{HIB\_HIGH}$	Internal 32.768 KHz clock reference rising edge to /HIB deasserted	-	30	-	$\mu s$
H3	$t_{WAKE\_ASSERT}$	/WAKE assertion time	62	-	-	$\mu s$
H4	$t_{WAKETOHIB}$	/WAKE assert to /HIB deassert	62	-	124	$\mu s$
H5	$t_{XOSC\_SETTLE}$	XOSC settling time <sup>a</sup>	20	-	-	ms
H6	$t_{HIB\_REG\_ACCESS}$	Access time to or from a non-volatile register in HIB module to complete	92	-	-	$\mu s$
H7	$t_{HIB\_TO\_VDD}$	$\overline{HIB}$ deassert to VDD and VDD25 at minimum operational level	-	-	250	$\mu s$

a. This parameter is highly sensitive to PCB layout and trace lengths, which may make this parameter time longer. Care must be taken in PCB design to minimize trace lengths and RLC (resistance, inductance, capacitance).

**Figure 23-9. Hibernation Module Timing**

### 23.2.7 General-Purpose I/O (GPIO)

**Note:** All GPIOs are 5 V-tolerant.

**Table 23-18. GPIO Characteristics**

Parameter	Parameter Name	Condition	Min	Nom	Max	Unit
$t_{GPIOR}$	GPIO Rise Time (from 20% to 80% of $V_{DD}$ )	2-mA drive	-	17	26	ns
		4-mA drive		9	13	ns
		8-mA drive		6	9	ns
		8-mA drive with slew rate control		10	12	ns
$t_{GPIOF}$	GPIO Fall Time (from 80% to 20% of $V_{DD}$ )	2-mA drive	-	17	25	ns
		4-mA drive		8	12	ns
		8-mA drive		6	10	ns
		8-mA drive with slew rate control		11	13	ns

### 23.2.8 Analog-to-Digital Converter

Table 23-19. ADC Characteristics<sup>a</sup>

Parameter	Parameter Name	Min	Nom	Max	Unit
$V_{ADCIN}$	Maximum single-ended, full-scale analog input voltage	-	-	3.0	V
	Minimum single-ended, full-scale analog input voltage	0.0	-	-	V
	Maximum differential, full-scale analog input voltage	-	-	1.5	V
	Minimum differential, full-scale analog input voltage	0.0	-	-	V
N	Resolution		10		bits
$f_{ADC}$	ADC internal clock frequency <sup>b</sup>	14	16	18	MHz
$t_{ADCCONV}$	Conversion time <sup>c</sup>				μs
$f_{ADCCONV}$	Conversion rate <sup>c</sup>				k samples/s
$t_{LT}$	Latency from trigger to start of conversion	-	2	-	system clocks
$I_L$	ADC input leakage	-	-	$\pm 3.0$	μA
$R_{ADC}$	ADC equivalent resistance	-	-	10	kΩ
$C_{ADC}$	ADC equivalent capacitance	0.9	1.0	1.1	pF
$E_L$	Integral nonlinearity error	-	-	$\pm 3$	LSB
$E_D$	Differential nonlinearity error	-	-	$\pm 2$	LSB
$E_O$	Offset error	-	-	$+6^d$	LSB
$E_G$	Full-scale gain error	-	-	$\pm 3$	LSB
$E_{TS}$	Temperature sensor accuracy	-	-	$\pm 5$	°C

a. The ADC reference voltage is 3.0 V. This reference voltage is internally generated from the 3.3 VDDA supply by a band gap circuit.

b. The ADC must be clocked from the PLL or directly from an external clock source to operate properly.

c. The conversion time and rate scale from the specified number if the ADC internal clock frequency is any value other than 16 MHz.

d. The offset error listed above is the conversion result with 0 V applied to the ADC input.

Figure 23-10. ADC Input Equivalency Diagram

**Table 23-20. ADC Module Internal Reference Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
$V_{REFI}$	Internal voltage reference for ADC	-	3.0	-	V
$E_{IR}$	Internal voltage reference error	-	-	$\pm 2.5$	%

### 23.2.9 Synchronous Serial Interface (SSI)

**Table 23-21. SSI Characteristics**

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
S1	$t_{clk\_per}$	SSIClk cycle time	2	-	65024	system clocks
S2	$t_{clk\_high}$	SSIClk high time	-	0.5	-	$t_{clk\_per}$
S3	$t_{clk\_low}$	SSIClk low time	-	0.5	-	$t_{clk\_per}$
S4	$t_{clkrf}$	SSIClk rise/fall time <sup>a</sup>	-	6	10	ns
S5	$t_{DMd}$	Data from master valid delay time	0	-	1	system clocks
S6	$t_{DMs}$	Data from master setup time	1	-	-	system clocks
S7	$t_{DMh}$	Data from master hold time	2	-	-	system clocks
S8	$t_{DSs}$	Data from slave setup time	1	-	-	system clocks
S9	$t_{DSh}$	Data from slave hold time	2	-	-	system clocks

a. Note that the delays shown are using 8-mA drive strength.

**Figure 23-11. SSI Timing for TI Frame Format (FRF=01), Single Transfer Timing Measurement**

**Figure 23-12. SSI Timing for MICROWIRE Frame Format (FRF=10), Single Transfer****Figure 23-13. SSI Timing for SPI Frame Format (FRF=00), with SPH=1**

### 23.2.10 Inter-Integrated Circuit ( $I^2C$ ) Interface

**Table 23-22.  $I^2C$  Characteristics**

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
I1 <sup>a</sup>	t <sub>SCH</sub>	Start condition hold time	36	-	-	system clocks
I2 <sup>a</sup>	t <sub>LP</sub>	Clock Low period	36	-	-	system clocks
I3 <sup>b</sup>	t <sub>SRT</sub>	I <sub>2</sub> CSCL/I <sub>2</sub> CSDA rise time ( $V_{IL} = 0.5\text{ V}$ to $V_{IH} = 2.4\text{ V}$ )	-	-	(see note b)	ns

**Table 23-22. I<sup>2</sup>C Characteristics (continued)**

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
I4 <sup>a</sup>	t <sub>DH</sub>	Data hold time	2	-	-	system clocks
I5 <sup>c</sup>	t <sub>SFT</sub>	I <sup>2</sup> CSCL/I <sup>2</sup> CSDA fall time ( $V_{IH} = 2.4\text{ V}$ to $V_{IL} = 0.5\text{ V}$ )	-	9	10	ns
I6 <sup>a</sup>	t <sub>HT</sub>	Clock High time	24	-	-	system clocks
I7 <sup>a</sup>	t <sub>DS</sub>	Data setup time	18	-	-	system clocks
I8 <sup>a</sup>	t <sub>SCSR</sub>	Start condition setup time (for repeated start condition only)	36	-	-	system clocks
I9 <sup>a</sup>	t <sub>SCS</sub>	Stop condition setup time	24	-	-	system clocks

- a. Values depend on the value programmed into the TPR bit in the **I<sup>2</sup>C Master Timer Period (I<sup>2</sup>CMTTPR)** register; a TPR programmed for the maximum I<sup>2</sup>CSCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I<sup>2</sup>CSCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I<sup>2</sup>CSCL and I<sup>2</sup>CSDA are open-drain-type outputs, which the controller can only actively drive Low, the time I<sup>2</sup>CSCL or I<sup>2</sup>CSDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

**Figure 23-14. I<sup>2</sup>C Timing**

### 23.2.11 Universal Serial Bus (USB) Controller

The Stellaris USB controller AC electrical specifications are compliant with the “Universal Serial Bus Specification Rev. 2.0” (full-speed and low-speed support).

### 23.2.12 Analog Comparator

**Table 23-23. Analog Comparator Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
V <sub>OS</sub>	Input offset voltage	-	±10	±25	mV
V <sub>CM</sub>	Input common mode voltage range	0	-	V <sub>DD</sub> -1.5	V
C <sub>MRR</sub>	Common mode rejection ratio	50	-	-	dB
T <sub>RT</sub>	Response time	-	-	1	μs
T <sub>MC</sub>	Comparator mode change to Output Valid	-	-	10	μs

**Table 23-24. Analog Comparator Voltage Reference Characteristics**

Parameter	Parameter Name	Min	Nom	Max	Unit
R <sub>HR</sub>	Resolution high range	-	V <sub>DD</sub> /31	-	LSB
R <sub>LR</sub>	Resolution low range	-	V <sub>DD</sub> /23	-	LSB

**Table 23-24. Analog Comparator Voltage Reference Characteristics (continued)**

Parameter	Parameter Name	Min	Nom	Max	Unit
$A_{HR}$	Absolute accuracy high range	-	-	$\pm 1/2$	LSB
$A_{LR}$	Absolute accuracy low range	-	-	$\pm 1/4$	LSB

# A Boot Loader

## A.1 Boot Loader

The Stellaris® Boot Loader is executed from the ROM when flash is empty and is used to download code to the flash memory of a device without the use of a debug interface. The boot loader uses a simple packet interface to provide synchronous communication with the device. The boot loader runs off the internal oscillator and does not enable the PLL, so its speed is determined by the speed of the internal oscillator. The following serial interfaces can be used:

- UART0
- SSI0
- I<sup>2</sup>C0

For simplicity, both the data format and communication protocol are identical for all serial interfaces.

See the *Stellaris Boot Loader User's Guide* for information on the boot loader software.

## A.2 Interfaces

Once communication with the boot loader is established via one of the serial interfaces, that interface is used until the boot loader is reset or new code takes over. For example, once you start communicating using the SSI port, communications with the boot loader via the UART are disabled until the device is reset.

### A.2.1 UART

The Universal Asynchronous Receivers/Transmitters (UART) communication uses a fixed serial format of 8 bits of data, no parity, and 1 stop bit. The baud rate used for communication is automatically detected by the boot loader and can be any valid baud rate supported by the host and the device. The auto detection sequence requires that the baud rate should be no more than 1/32 the internal oscillator frequency of the board that is running the boot loader (which is at least 8.4 MHz, providing support for up to 262,500 baud). This is actually the same as the hardware limitation for the maximum baud rate for any UART on a Stellaris device which is calculated as follows:

$$\text{Max Baud Rate} = \text{System Clock Frequency} / 16$$

In order to determine the baud rate, the boot loader needs to determine the relationship between the internal oscillator and the baud rate. This is enough information for the boot loader to configure its UART to the same baud rate as the host. This automatic baud-rate detection allows the host to use any valid baud rate that it wants to communicate with the device.

The method used to perform this automatic synchronization relies on the host sending the boot loader two bytes that are both 0x55. This generates a series of pulses to the boot loader that it can use to calculate the ratios needed to program the UART to match the host's baud rate. After the host sends the pattern, it attempts to read back one byte of data from the UART. The boot loader returns the value of 0xCC to indicate successful detection of the baud rate. If this byte is not received after at least twice the time required to transfer the two bytes, the host can resend another pattern of 0x55, 0x55, and wait for the 0xCC byte again until the boot loader acknowledges that it has received a synchronization pattern correctly. For example, the time to wait for data back from the boot loader should be calculated as at least  $2 * (20(\text{bits}/\text{sync})/\text{baud rate} (\text{bits}/\text{sec}))$ . For a baud rate of 115200, this time is  $2 * (20/115200)$  or 0.35 ms.

### A.2.2 SSI

The Synchronous Serial Interface (SSI) port also uses a fixed serial format for communications, with the framing defined as Motorola format with SPH set to 1 and SPO set to 1. See “Frame Formats” on page 546 in the SSI chapter for more information on formats for this transfer protocol. Like the UART, this interface has hardware requirements that limit the maximum speed that the SSI clock can run. This allows the SSI clock to be at most 1/12 the internal oscillator frequency of the board running the boot loader (which is at least 8.4 MHz, providing support for up to 700 KHz).. Since the host device is the master, the SSI on the boot loader device does not need to determine the clock as it is provided directly by the host.

### A.2.3 I<sup>2</sup>C

The Inter-Integrated Circuit (I<sup>2</sup>C) port operates in slave mode with a slave address of 0x42. The I<sup>2</sup>C port will work at both 100 KHz and 400 KHz I<sup>2</sup>C clock frequency. Since the host device is the master, the I<sup>2</sup>C on the boot loader device does not need to determine the clock as it is provided directly by the host.

## A.3 Packet Handling

All communications, with the exception of the UART auto-baud, are done via defined packets that are acknowledged (ACK) or not acknowledged (NAK) by the devices. The packets use the same format for receiving and sending packets, including the method used to acknowledge successful or unsuccessful reception of a packet.

### A.3.1 Packet Format

All packets sent and received from the device use the following byte-packed format.

```
struct
{
    unsigned char ucSize;
    unsigned char ucCheckSum;
    unsigned char Data[];
};
```

ucSize	The first byte received holds the total size of the transfer including the size and checksum bytes.
ucChecksum	This holds a simple checksum of the bytes in the data buffer only. The algorithm is Data[0]+Data[1]+...+ Data[ucSize-3].
Data	This is the raw data intended for the device, which is formatted in some form of command interface. There should be ucSize-2 bytes of data provided in this buffer to or from the device.

### A.3.2 Sending Packets

The actual bytes of the packet can be sent individually or all at once; the only limitation is that commands that cause flash memory access should limit the download sizes to prevent losing bytes during flash programming. This limitation is discussed further in the section that describes the boot loader command, COMMAND\_SEND\_DATA (see “COMMAND\_SEND\_DATA (0x24)” on page 828).

Once the packet has been formatted correctly by the host, it should be sent out over the UART or SSI interface. Then the host should poll the UART or SSI interface for the first non-zero data returned from the device. The first non-zero byte will either be an ACK (0xCC) or a NAK (0x33) byte from

the device indicating the packet was received successfully (ACK) or unsuccessfully (NAK). This does not indicate that the actual contents of the command issued in the data portion of the packet were valid, just that the packet was received correctly.

### A.3.3 Receiving Packets

The boot loader sends a packet of data in the same format that it receives a packet. The boot loader may transfer leading zero data before the first actual byte of data is sent out. The first non-zero byte is the size of the packet followed by a checksum byte, and finally followed by the data itself. There is no break in the data after the first non-zero byte is sent from the boot loader. Once the device communicating with the boot loader receives all the bytes, it must either ACK or NAK the packet to indicate that the transmission was successful. The appropriate response after sending a NAK to the boot loader is to resend the command that failed and request the data again. If needed, the host may send leading zeros before sending down the ACK/NAK signal to the boot loader, as the boot loader only accepts the first non-zero data as a valid response. This zero padding is needed by the SSI interface in order to receive data to or from the boot loader.

## A.4 Commands

The next section defines the list of commands that can be sent to the boot loader. The first byte of the data should always be one of the defined commands, followed by data or parameters as determined by the command that is sent.

### A.4.1 COMMAND\_PING (0x20)

This command simply accepts the command and sets the global status to success. The format of the packet is as follows:

```
Byte[0] = 0x03;
Byte[1] = checksum(Byte[2]);
Byte[2] = COMMAND_PING;
```

The ping command has 3 bytes and the value for COMMAND\_PING is 0x20 and the checksum of one byte is that same byte, making Byte[1] also 0x20. Since the ping command has no real return status, the receipt of an ACK can be interpreted as a successful ping to the boot loader.

### A.4.2 COMMAND\_DOWNLOAD (0x21)

This command is sent to the boot loader to indicate where to store data and how many bytes will be sent by the COMMAND\_SEND\_DATA commands that follow. The command consists of two 32-bit values that are both transferred MSB first. The first 32-bit value is the address to start programming data into, while the second is the 32-bit size of the data that will be sent. This command also triggers an erase of the full area to be programmed so this command takes longer than other commands. This results in a longer time to receive the ACK/NAK back from the board. This command should be followed by a COMMAND\_GET\_STATUS to ensure that the Program Address and Program size are valid for the device running the boot loader.

The format of the packet to send this command is as follows:

```
Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_DOWNLOAD
Byte[3] = Program Address [31:24]
Byte[4] = Program Address [23:16]
Byte[5] = Program Address [15:8]
```

```
Byte[6] = Program Address [7:0]
Byte[7] = Program Size [31:24]
Byte[8] = Program Size [23:16]
Byte[9] = Program Size [15:8]
Byte[10] = Program Size [7:0]
```

#### A.4.3 **COMMAND\_RUN (0x22)**

This command is used to tell the boot loader to execute from the address passed as the parameter in this command. This command consists of a single 32-bit value that is interpreted as the address to execute. The 32-bit value is transmitted MSB first and the boot loader responds with an ACK signal back to the host device before actually executing the code at the given address. This allows the host to know that the command was received successfully and the code is now running.

```
Byte[0] = 7
Byte[1] = checksum(Bytes[2:6])
Byte[2] = COMMAND_RUN
Byte[3] = Execute Address[31:24]
Byte[4] = Execute Address[23:16]
Byte[5] = Execute Address[15:8]
Byte[6] = Execute Address[7:0]
```

#### A.4.4 **COMMAND\_GET\_STATUS (0x23)**

This command returns the status of the last command that was issued. Typically, this command should be sent after every command to ensure that the previous command was successful or to properly respond to a failure. The command requires one byte in the data of the packet and should be followed by reading a packet with one byte of data that contains a status code. The last step is to ACK or NAK the received data so the boot loader knows that the data has been read.

```
Byte[0] = 0x03
Byte[1] = checksum(Byte[2])
Byte[2] = COMMAND_GET_STATUS
```

#### A.4.5 **COMMAND\_SEND\_DATA (0x24)**

This command should only follow a COMMAND\_DOWNLOAD command or another COMMAND\_SEND\_DATA command if more data is needed. Consecutive send data commands automatically increment address and continue programming from the previous location. For packets which do not contain the final portion of the downloaded data, a multiple of four bytes should always be transferred. The command terminates programming once the number of bytes indicated by the COMMAND\_DOWNLOAD command has been received. Each time this function is called it should be followed by a COMMAND\_GET\_STATUS to ensure that the data was successfully programmed into the flash. If the boot loader sends a NAK to this command, the boot loader does not increment the current address to allow retransmission of the previous data. The following example shows a COMMAND\_SEND\_DATA packet with 8 bytes of packet data:

```
Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_SEND_DATA
Byte[3] = Data[0]
Byte[4] = Data[1]
Byte[5] = Data[2]
Byte[6] = Data[3]
```

```
Byte[7] = Data[4]
Byte[8] = Data[5]
Byte[9] = Data[6]
Byte[10] = Data[7]
```

#### A.4.6 COMMAND\_RESET (0x25)

This command is used to tell the boot loader device to reset. Unlike the COMMAND\_RUN command, this allows the initial stack pointer to be read by the hardware and set up for the new code. It can also be used to reset the boot loader if a critical error occurs and the host device wants to restart communication with the boot loader.

```
Byte[0] = 3
Byte[1] = checksum(Byte[2])
Byte[2] = COMMAND_RESET
```

The boot loader responds with an ACK signal back to the host device before actually executing the software reset to the device running the boot loader. This allows the host to know that the command was received successfully and the part will be reset.

## B ROM DriverLib Functions

### B.1 DriverLib Functions Included in the Integrated ROM

The Stellaris® Peripheral Driver Library (DriverLib) APIs that are available in the integrated ROM of the Stellaris family of devices are listed below. The detailed description of each function is available in the *Stellaris® ROM User's Guide*.

```
ROM_ADCHardwareOversampleConfigure
    // Configures the hardware oversampling factor of the ADC.

ROM_ADCIntClear
    // Clears sample sequence interrupt source.

ROM_ADCIntDisable
    // Disables a sample sequence interrupt.

ROM_ADCIntEnable
    // Enables a sample sequence interrupt.

ROM_ADCIntStatus
    // Gets the current interrupt status.

ROM_ADCProcessorTrigger
    // Causes a processor trigger for a sample sequence.

ROM_ADCSequenceConfigure
    // Configures the trigger source and priority of a sample sequence.

ROM_ADCSequenceDataGet
    // Gets the captured data for a sample sequence.

ROM_ADCSequenceDisable
    // Disables a sample sequence.

ROM_ADCSequenceEnable
    // Enables a sample sequence.

ROM_ADCSequenceOverflow
    // Determines if a sample sequence overflow occurred.

ROM_ADCSequenceOverflowClear
    // Clears the overflow condition on a sample sequence.

ROM_ADCSequenceStepConfigure
    // Configure a step of the sample sequencer.

ROM_ADCSequenceUnderflow
    // Determines if a sample sequence underflow occurred.

ROM_ADCSequenceUnderflowClear
    // Clears the underflow condition on a sample sequence.
```

```
ROM_ComparatorConfigure
// Configures a comparator.

ROM_ComparatorIntClear
// Clears a comparator interrupt.

ROM_ComparatorIntDisable
// Disables the comparator interrupt.

ROM_ComparatorIntEnable
// Enables the comparator interrupt.

ROM_ComparatorIntStatus
// Gets the current interrupt status.

ROM_ComparatorRefSet
// Sets the internal reference voltage.

ROM_ComparatorValueGet
// Gets the current comparator output value.

ROM_FlashErase
// Erases a block of flash.

ROM_FlashIntClear
// Clears flash controller interrupt sources.

ROM_FlashIntDisable
// Disables individual flash controller interrupt sources.

ROM_FlashIntEnable
// Enables individual flash controller interrupt sources.

ROM_FlashIntGetStatus
// Gets the current interrupt status.

ROM_FlashProgram
// Programs flash.

ROM_FlashProtectGet
// Gets the protection setting for a block of flash.

ROM_FlashProtectSave
// Saves the flash protection settings.

ROM_FlashProtectSet
// Sets the protection setting for a block of flash.

ROM_FlashUsecGet
// Gets the number of processor clocks per micro-second.

ROM_FlashUsecSet
// Sets the number of processor clocks per micro-second.
```

```
ROM_FlashUserGet
    // Gets the user registers.

ROM_FlashUserSave
    // Saves the user registers.

ROM_FlashUserSet
    // Sets the user registers.

ROM_GPIODirModeGet
    // Gets the direction and mode of a pin.

ROM_GPIODirModeSet
    // Sets the direction and mode of the specified pin(s).

ROM_GPIOIntTypeGet
    // Gets the interrupt type for a pin.

ROM_GPIOIntTypeSet
    // Sets the interrupt type for the specified pin(s).

ROM_GPIOPadConfigGet
    // Gets the pad configuration for a pin.

ROM_GPIOPadConfigSet
    // Sets the pad configuration for the specified pin(s).

ROM_GPIOPinIntClear
    // Clears the interrupt for the specified pin(s).

ROM_GPIOPinIntDisable
    // Disables interrupts for the specified pin(s).

ROM_GPIOPinIntEnable
    // Enables interrupts for the specified pin(s).

ROM_GPIOPinIntStatus
    // Gets interrupt status for the specified GPIO port.

ROM_GPIOPinRead
    // Reads the values present of the specified pin(s).

ROM_GPIOPinTypeComparator
    // Configures pin(s) for use as an analog comparator input.

ROM_GPIOPinTypeGPIOInput
    // Configures pin(s) for use as GPIO inputs.

ROM_GPIOPinTypeGPIOOutput
    // Configures pin(s) for use as GPIO outputs.

ROM_GPIOPinTypeGPIOOutputOD
    // Configures pin(s) for use as GPIO open drain outputs.
```

```
ROM_GPIOPinTypeI2C
// Configures pin(s) for use by the I2C peripheral.

ROM_GPIOPinTypePWM
// Configures pin(s) for use by the PWM peripheral.

ROM_GPIOPinTypeQEI
// Configures pin(s) for use by the QEI peripheral.

ROM_GPIOPinTypeSSI
// Configures pin(s) for use by the SSI peripheral.

ROM_GPIOPinTypeTimer
// Configures pin(s) for use by the Timer peripheral.

ROM_GPIOPinTypeUART
// Configures pin(s) for use by the UART peripheral.

ROM_GPIOPinWrite
// Writes a value to the specified pin(s).

ROM_I2CMasterBusBusy
// Indicates whether or not the I2C bus is busy.

ROM_I2CMasterBusy
// Indicates whether or not the I2C Master is busy.

ROM_I2CMasterControl
// Controls the state of the I2C Master module.

ROM_I2CMasterDataGet
// Receives a byte that has been sent to the I2C Master.

ROM_I2CMasterDataPut
// Transmits a byte from the I2C Master.

ROM_I2CMasterDisable
// Disables the I2C master block.

ROM_I2CMasterEnable
// Enables the I2C Master block.

ROM_I2CMasterErr
// Gets the error status of the I2C Master module.

ROM_I2CMasterInitExpClk
// Initializes the I2C Master block.

ROM_I2CMasterIntClear
// Clears I2C Master interrupt sources.

ROM_I2CMasterIntDisable
// Disables the I2C Master interrupt.
```

```
ROM_I2CMasterIntEnable
    // Enables the I2C Master interrupt.

ROM_I2CMasterIntStatus
    // Gets the current I2C Master interrupt status.

ROM_I2CMasterSlaveAddrSet
    // Sets the address that the I2C Master will place on the bus.

ROM_I2CSlaveDataGet
    // Receives a byte that has been sent to the I2C Slave.

ROM_I2CSlaveDataPut
    // Transmits a byte from the I2C Slave.

ROM_I2CSlaveDisable
    // Disables the I2C slave block.

ROM_I2CSlaveEnable
    // Enables the I2C Slave block.

ROM_I2CSlaveInit
    // Initializes the I2C Slave block.

ROM_I2CSlaveIntClear
    // Clears I2C Slave interrupt sources.

ROM_I2CSlaveIntDisable
    // Disables the I2C Slave interrupt.

ROM_I2CSlaveIntEnable
    // Enables the I2C Slave interrupt.

ROM_I2CSlaveIntStatus
    // Gets the current I2C Slave interrupt status.

ROM_I2CSlaveStatus
    // Gets the I2C Slave module status.

ROM_IntDisable
    // Disables an interrupt.

ROM_IntEnable
    // Enables an interrupt.

ROM_IntPriorityGet
    // Gets the priority of an interrupt.

ROM_IntPriorityGroupingGet
    // Gets the priority grouping of the interrupt controller.

ROM_IntPriorityGroupingSet
    // Sets the priority grouping of the interrupt controller.
```

```

ROM_IntPrioritySet
// Sets the priority of an interrupt.

ROM_PWMDeadBandDisable
// Disables the PWM dead band output.

ROM_PWMDeadBandEnable
// Enables the PWM dead band output, and sets the dead band delays.

ROM_PWMFaultIntClear
// Clears the fault interrupt for a PWM module.

ROM_PWMGenConfigure
// Configures a PWM generator.

ROM_PWMGenDisable
// Disables the timer/counter for a PWM generator block.

ROM_PWMGenEnable
// Enables the timer/counter for a PWM generator block.

ROM_PWMGenIntClear
// Clears the specified interrupt(s) for the specified PWM generator block.

ROM_PWMGenIntStatus
// Gets interrupt status for the specified PWM generator block.

ROM_PWMGenIntTrigDisable
// Disables interrupts for the specified PWM generator block.

ROM_PWMGenIntTrigEnable
// Enables interrupts and triggers for the specified PWM generator block.

ROM_PWMGenPeriodGet
// Gets the period of a PWM generator block.

ROM_PWMGenPeriodSet
// Set the period of a PWM generator.

ROM_PWMIntDisable
// Disables generator and fault interrupts for a PWM module.

ROM_PWMIntEnable
// Enables generator and fault interrupts for a PWM module.

ROM_PWMIntStatus
// Gets the interrupt status for a PWM module.

ROM_PWMOutputFault
// Specifies the state of PWM outputs in response to a fault condition.

ROM_PWMOutputInvert
// Selects the inversion mode for PWM outputs.

```

```
ROM_PWMOutputState  
    // Enables or disables PWM outputs.  
  
ROM_PWMWidthGet  
    // Gets the pulse width of a PWM output.  
  
ROM_PWMWidthSet  
    // Sets the pulse width for the specified PWM output.  
  
ROM_PWMSyncTimeBase  
    // Synchronizes the counters in one or multiple PWM generator blocks.  
  
ROM_PWMSyncUpdate  
    // Synchronizes all pending updates.  
  
ROM_QEIConfigure  
    // Configures the quadrature encoder.  
  
ROM_QEIDirectionGet  
    // Gets the current direction of rotation.  
  
ROM_QEIDisable  
    // Disables the quadrature encoder.  
  
ROM_QEIEnable  
    // Enables the quadrature encoder.  
  
ROM_QEIErrorGet  
    // Gets the encoder error indicator.  
  
ROM_QEIIntClear  
    // Clears quadrature encoder interrupt sources.  
  
ROM_QEIIntDisable  
    // Disables individual quadrature encoder interrupt sources.  
  
ROM_QEIIntEnable  
    // Enables individual quadrature encoder interrupt sources.  
  
ROM_QEIIntStatus  
    // Gets the current interrupt status.  
  
ROM_QEIPositionGet  
    // Gets the current encoder position.  
  
ROM_QEIPositionSet  
    // Sets the current encoder position.  
  
ROM_QEIVelocityConfigure  
    // Configures the velocity capture.  
  
ROM_QEIVelocityDisable  
    // Disables the velocity capture.
```

```
ROM_QEIVelocityEnable
// Enables the velocity capture.

ROM_QEIVelocityGet
// Gets the current encoder speed.

ROM_SSIConfigSetExpClk
// Configures the synchronous serial interface.

ROM_SSIDataGet
// Gets a data element from the SSI receive FIFO.

ROM_SSIDataGetNonBlocking
// Gets a data element from the SSI receive FIFO.

ROM_SSIDataPut
// Puts a data element into the SSI transmit FIFO.

ROM_SSIDataPutNonBlocking
// Puts a data element into the SSI transmit FIFO.

ROM_SSIDisable
// Disables the synchronous serial interface.

ROM_SSIEnable
// Enables the synchronous serial interface.

ROM_SSIntlClear
// Clears SSI interrupt sources.

ROM_SSIntlDisable
// Disables individual SSI interrupt sources.

ROM_SSIntlEnable
// Enables individual SSI interrupt sources.

ROM_SSIntlStatus
// Gets the current interrupt status.

ROM_SysCtlADCSSpeedGet
// Gets the sample rate of the ADC.

ROM_SysCtlADCSSpeedSet
// Sets the sample rate of the ADC.

ROM_SysCtlClockGet
// Gets the processor clock rate.

ROM_SysCtlClockSet
// Sets the clocking of the device.

ROM_SysCtlDeepSleep
// Puts the processor into deep-sleep mode.
```

```
ROM_SysCtlFlashSizeGet
    // Gets the size of the flash.

ROM_SysCtlGPIOAHBDisable
    // Disables a GPIO peripheral for access from the AHB.

ROM_SysCtlGPIOAHBEnable
    // Enables a GPIO peripheral for access from the AHB.

ROM_SysCtlIntClear
    // Clears system control interrupt sources.

ROM_SysCtlIntDisable
    // Disables individual system control interrupt sources.

ROM_SysCtlIntEnable
    // Enables individual system control interrupt sources.

ROM_SysCtlIntStatus
    // Gets the current interrupt status.

ROM_SysCtlLDOGet
    // Gets the output voltage of the LDO.

ROM_SysCtlLDOSet
    // Sets the output voltage of the LDO.

ROM_SysCtlPeripheralClockGating
    // Controls peripheral clock gating in sleep and deep-sleep mode.

ROM_SysCtlPeripheralDeepSleepDisable
    // Disables a peripheral in deep-sleep mode.

ROM_SysCtlPeripheralDeepSleepEnable
    // Enables a peripheral in deep-sleep mode.

ROM_SysCtlPeripheralDisable
    // Disables a peripheral.

ROM_SysCtlPeripheralEnable
    // Enables a peripheral.

ROM_SysCtlPeripheralPresent
    // Determines if a peripheral is present.

ROM_SysCtlPeripheralReset
    // Performs a software reset of a peripheral.

ROM_SysCtlPeripheralSleepDisable
    // Disables a peripheral in sleep mode.

ROM_SysCtlPeripheralSleepEnable
    // Enables a peripheral in sleep mode.
```

```
ROM_SysCtlPinPresent
// Determines if a pin is present.

ROM_SysCtlPWMClockGet
// Gets the current PWM clock configuration.

ROM_SysCtlPWMClockSet
// Sets the PWM clock configuration.

ROM_SysCtlReset
// Resets the device.

ROM_SysCtlResetCauseClear
// Clears reset reasons.

ROM_SysCtlResetCauseGet
// Gets the reason for a reset.

ROM_SysCtlSleep
// Puts the processor into sleep mode.

ROM_SysCtlSRAMSizeGet
// Gets the size of the SRAM.

ROM_SysTickDisable
// Disables the SysTick counter.

ROM_SysTickEnable
// Enables the SysTick counter.

ROM_SysTickIntDisable
// Disables the SysTick interrupt.

ROM_SysTickIntEnable
// Enables the SysTick interrupt.

ROM_SysTickPeriodGet
// Gets the period of the SysTick counter.

ROM_SysTickPeriodSet
// Sets the period of the SysTick counter.

ROM_SysTickValueGet
// Gets the current value of the SysTick counter.

ROM_TimerConfigure
// Configures the timer(s).

ROM_TimerControlEvent
// Controls the event type.

ROM_TimerControlLevel
// Controls the output level.
```

```
ROM_TimerControlStall
    // Controls the stall handling.

ROM_TimerControlTrigger
    // Enables or disables the trigger output.

ROM_TimerDisable
    // Disables the timer(s).

ROM_TimerEnable
    // Enables the timer(s).

ROM_TimerIntClear
    // Clears timer interrupt sources.

ROM_TimerIntDisable
    // Disables individual timer interrupt sources.

ROM_TimerIntEnable
    // Enables individual timer interrupt sources.

ROM_TimerIntStatus
    // Gets the current interrupt status.

ROM_TimerLoadGet
    // Gets the timer load value.

ROM_TimerLoadSet
    // Sets the timer load value.

ROM_TimerMatchGet
    // Gets the timer match value.

ROM_TimerMatchSet
    // Sets the timer match value.

ROM_TimerPrescaleGet
    // Get the timer prescale value.

ROM_TimerPrescaleSet
    // Set the timer prescale value.

ROM_TimerRTCDisable
    // Disable RTC counting.

ROM_TimerRTCEnable
    // Enable RTC counting.

ROM_TimerValueGet
    // Gets the current timer value.

ROM_UARTBreakCtl
    // Causes a BREAK to be sent.
```

```
ROM_UARTCharGet
// Waits for a character from the specified port.

ROM_UARTCharGetNonBlocking
// Receives a character from the specified port.

ROM_UARTCharPut
// Waits to send a character from the specified port.

ROM_UARTCharPutNonBlocking
// Sends a character to the specified port.

ROM_UARTCharsAvail
// Determines if there are any characters in the receive FIFO.

ROM_UARTConfigGetExpClk
// Gets the current configuration of a UART.

ROM_UARTConfigSetExpClk
// Sets the configuration of a UART.

ROM_UARTDisable
// Disables transmitting and receiving.

ROM_UARTDisableSIR
// Disables SIR (IrDA) mode on the specified UART.

ROM_UARTEnable
// Enables transmitting and receiving.

ROM_UARTEnableSIR
// Enables SIR (IrDA) mode on specified UART.

ROM_UARTFIFOLevelGet
// Gets the FIFO level at which interrupts are generated.

ROM_UARTFIFOLevelSet
// Sets the FIFO level at which interrupts are generated.

ROM_UARTIntClear
// Clears UART interrupt sources.

ROM_UARTIntDisable
// Disables individual UART interrupt sources.

ROM_UARTIntEnable
// Enables individual UART interrupt sources.

ROM_UARTIntStatus
// Gets the current interrupt status.

ROM_UARTParityModeGet
// Gets the type of parity currently being used.
```

```
ROM_UARTParityModeSet
    // Sets the type of parity.

ROM_UARTSpaceAvail
    // Determines if there is any space in the transmit FIFO.

ROM_UpdateI2C
    // Starts an update over the I2C0 interface.

ROM_UpdateSSI
    // Starts an update over the SSI0 interface.

ROM_UpdateUART
    // Starts an update over the UART0 interface.

ROM_WatchdogEnable
    // Enables the watchdog timer.

ROM_WatchdogIntClear
    // Clears the watchdog timer interrupt.

ROM_WatchdogIntEnable
    // Enables the watchdog timer interrupt.

ROM_WatchdogIntStatus
    // Gets the current watchdog timer interrupt status.

ROM_WatchdogLock
    // Enables the watchdog timer lock mechanism.

ROM_WatchdogLockState
    // Gets the state of the watchdog timer lock mechanism.

ROM_WatchdogReloadGet
    // Gets the watchdog timer reload value.

ROM_WatchdogReloadSet
    // Sets the watchdog timer reload value.

ROM_WatchdogResetDisable
    // Disables the watchdog timer reset.

ROM_WatchdogResetEnable
    // Enables the watchdog timer reset.

ROM_WatchdogRunning
    // Determines if the watchdog timer is enabled.

ROM_WatchdogStallDisable
    // Disables stalling of the watchdog timer during debug events.

ROM_WatchdogStallEnable
    // Enables stalling of the watchdog timer during debug events.
```

```
ROM_WatchdogUnlock  
// Disables the watchdog timer lock mechanism.  
  
ROM_WatchdogValueGet  
// Gets the current watchdog timer value.
```

## D Ordering and Contact Information

### D.1 Ordering Information

Table D-1. Part Ordering Information

Orderable Part Number	Description
LM3S3748-IQC50-A0	Stellaris® LM3S3748 Microcontroller Industrial Temperature 100-pin LQFP
LM3S3748-IQC50-A0T	Stellaris LM3S3748 Microcontroller Industrial Temperature 100-pin LQFP Tape-and-reel

### D.2 Part Markings

The Stellaris microcontrollers are marked with an identifying number. This code contains the following information:

- The first line indicates the part number. In the example figure below, this is the LM3S6965.
- In the second line, the first seven characters indicate the temperature, package, speed, and revision. In the example below, this is an Industrial temperature (I), 100-pin LQFP package (QC), 50-MHz (50), revision A2 (A2) device.
- The remaining characters contain internal tracking numbers.

### D.3 Kits

The Stellaris Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the website at [www.ti.com/stellaris](http://www.ti.com/stellaris) for the latest tools available, or ask your distributor.

## D.4 Support Information

For support on Stellaris products, contact the TI Worldwide Product Information Center nearest you:  
<http://www-k.ext.ti.com/sc/technical-support/product-information-centers.htm>.

# E Package Information

## E.1 100-Pin LQFP Package

### E.1.1 Package Dimensions

**Figure E-1. 100-Pin LQFP Package Dimensions**

**Note:** The following notes apply to the package drawing.

1. All dimensions shown in mm.
2. Dimensions shown are nominal with tolerances indicated.
3. Foot length 'L' is measured at gage plane 0.25 mm above seating plane.

Body +2.00 mm Footprint, 1.4 mm package thickness		
Symbols	Leads

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
